"*Resolved*, That the National Electric Light Association after a full discussion of the subject, desire to express their hearty sympathy with the views expressed by his Honor, Mayor Hewitt, in his address before the association upon the subject of putting wires underground, and in addition desire to take this mode of expressing the opinion that up to the present time no commercially practical method has ever been brought to their notice by which high tension direct currents such as are used for arc lighting can be placed underground."

The resolution was seconded by Mr. Lynch and carried.

A paper on "The Comparative Danger of Alternate vs. Direct Currents," by Professor P. H. Van der Weyde was read by Mr. Arthur Steuart.

THE COMPARATIVE DANGER OF ALTERNATE vs. DIRECT CURRENTS.

BY DR. P. H. VAN DER WEYDE.[1]

IT is only a few days ago that I received the flattering invitation to appear before this meeting of the most eminent electricians of the United States, and present a paper containing my conclusions about the comparative danger to life lurking in the alternate and direct dynamo currents. I do so readily, as I have lately had the opportunity to become acquainted with the arguments made on both sides of the question. I was not prepared to do so when, a few months ago, I attended a meeting of the New York Board of Electrical Control, where several papers were read, most of them in opposition to Mr. Harold P. Brown, who had expressed himself against the use of the alternate current system, of which the introduction has lately been commenced. When the president of that meeting asked me to express my opinion I was in the necessity to decline, stating that my appearance there was solely intended to listen to arguments upon the subject about which I desired full information.

As some of the papers read there were written in such a spirit as to compel Mr. Brown to defend himself, I made up my mind to attend his expected defense, especially as it might give me an opportunity to hear what powerful arguments and facts would be brought out by the person who has put himself forward as the champion of the enemies of the alternate current system.

It makes always a painful impression upon me when I see that a scientific investigator feels the necessity to defend himself against personal attacks. The calling of the scientist should simply be confined to ascertain what is the truth ; if he thinks to detect erroneous conclusions arrived at by any colaborer, it is his duty to expose them. At the same time we must mind the old rule, *suaviter in modo, fortiter in re ;* therefore, above all he must let the facts speak for themselves, avoiding any allusion regarding the capabilities or ulterior motives of his antagonist ; in short, he must leave the use of all personalities to the politicians ; for these the main considerations are *persons*, *principles* are secondary and may be changed to suit circumstances, or thrown overboard entirely. In science, however, we have to the contrary nothing to do with *persons*, but only with the ultimate *truth*, which we are all striving to arrive at.

At a recent visit to the physical lecture room of Columbia College, where I had been invited by telegram to hear the reading of a paper, and a lecture illustrated by experiments by Mr. Harold P. Brown, the feeling referred to above was more painful to me than even the howling of the dog which was experimented upon. Dogs have for so many years been considered as the poor legitimate martyrs of science, especially under the hands of physicians and professors of physiology, that we have become more or less hardened in their regard. Nobody will deny the immense value of the increase of our biological and especially pathological knowledge obtained in this way.

A great portion of the paper read by Mr. Brown, consisted in complaints about the personal attacks made upon his capability, as soon as he asserted in print that the alternate electric currents were more dangerous to human life than the direct currents, namely : that a current of the electromotive force of say 300 volts, alternate current, would be more likely to destroy life than double or triple that strength of a direct current.

One feature was prominent in the reading of the paper as well as in the lecture and experiments ; it was evident that the purpose was not so much to exhibit what was the truth in the matter as to show that he was right in what he had asserted.

He attempted to prove this by experimenting upon a large dog, which, when subjected to a direct current, stated to be 300 volts, set up a short howl ; 600 volts produced a longer howl and frantic efforts to escape from the cage, while a current of some 900 volts paralyzed the dog, who kept up a labored breathing. Then a representative of the New York Society for the Prevention of Cruelty to Animals interfered, and forbade further trials of this kind, so that Mr. Brown was compelled to give the dog the *coup de grace* by applying the alternate current, which he stated to be of the strength of only 300 volts.

Unfortunately for Mr. Brown this proved nothing, as the dog was already half dead by the previous successive and increasing direct current doses of 300, 600 and 900 volts respectively. Another dose of 300 or 600 volts direct current might, in all probability, have ended his life just as well. But what is more, his statement that the alternating current was merely 300 volts was not proved, as he himself had stated previously that reliable instruments for measuring alternate currents were difficult to obtain, and confessed that he had only a voltmeter for this purpose but no ammeter. After the lecture I examined the voltmeter, and found that according to the statements of Mr. Brown, its operation was based upon indications of rise in temperature.

Now, it is well known that rise of temperature is not produced by electromotive force, but by amount of current ; one Wollaston plunge battery cell, of one square meter acting surface, having, of course, the electromotive force of only one single volt, will produce far more heat

1. The unavoidable haste with which this paper was prepared resulted in a few inaccurate deductions, based on certain superficial examinations. Some of these were corrected in the paper as read, but unfortunately not incorporated in the weekly electrical journals, which in their praiseworthy endeavor to give an early report of the meeting, had the first half of the paper in type before it was read, and could not detain their publication to make the corrections referred to as fully as desirable.

The ELECTRICAL ENGINEER being a monthly publication, allows time for correction, and having adopted the excellent plan of submitting the proofs to the writers for ultimate correction, I take advantage of this opportunity to obtain a more full and correct record of my paper as I intended it to be.—P. H. VAN DER WEYDE.

than a series of 24 freshly prepared cups of a Leclanché battery of 40 volts electromotive force. This voltmeter was perhaps a kind of ammeter.

This was the opinion of Professor G. Forbes, from England, who last year exhibited to the Society of Electrical Engineers, in New York, a meter for alternating currents; he did not call it a voltmeter, because its operation was also based upon rise of temperature, but he called it a current meter. This meter was described and illustrated on page 1, of the *Electrical Review*, for October 8, 1887, where there is added a little table giving the observed currents in amperes. Immediately under that table follows the statement that Sir William Thomson complimented the author on having practically solved a problem on which he himself had been working without satisfactory results, thus endorsing the instrument as a current or ampere meter.

If, however, such an instrument is carefully gauged in regard to resistance, so as to satisfy the formula volt = am. × res., it may be converted into a voltmeter; but instruments of this kind are not always properly gauged in this way, and are frequently unreliable.

And here I cannot let the opportunity pass by to repeat what I have been preaching for years, namely, that the voltage alone is no criterion in regard to the dangerousness of a current; the danger comes only when the electromotive force (as measured in volts) is accompanied by a sufficient quantity or volume of current (as measured in amperes). An electromotive force carrying a current of only a few micro-amperes may be as high as 1,000 volts without doing any harm (even when alternating, as proved by the Rhumkorff coil). It behaves like water oozing out of a pinhole under pressure of hundreds of pounds; it can do little or no work. At the other side, a very large volume or quantity of current with small electromotive force, of say a small fraction of a volt, will not have the power to pass through the human skin, or even through the liquids of the body, but only through metals (as proved by the thermo-electric pile). Such currents behave like a large volume of water in a lake, with little or no inducement to make it move; also, this will do little or no work.

Professor Mayer, of the Stevens Institute, Hoboken, in a lecture recently given to the members of the electric section of the American Institute, exhibited some novel experiments, intended to measure, if possible, the voltage of static currents. He used an old-fashioned friction electric machine, and showed that the voltage of its currents ran into the thousands, while the amperes were so minute as to escape the possibility of measurement, with the means thus far at disposal.

This leads me back to the subject of the experiments of Mr. Brown; he stated that the quantity of the direct current he used was only a fraction of one ampere. This induced me to examine also the ammeter after the lecture, when I found that the ammeter and voltmeter were coupled together in series in the same single circuit. I did not see any switches connected therewith, so as to shunt out the high resistance of the voltmeter when the current was applied, as is frequently customary; therefore I concluded that the direct current had the benefit of being moderated by this resistance also, which benefit was not given to the alternating current for reason of the absence of this high resistance in its circuit, and in place, therefore, the much lower resistance of the alternating ammeter referred to above. When after the lecture I visited the dynamo plant of Columbia College to inquire, I found that the direct current machine used was an Edison municipal dynamo of 15 amperes and 1200 volts.

It is likely that Mr. Edison gave it the name of municipal in anticipation of the fact that the municipal governments will need such machines when the new law in regard to capital punishment and of despatching criminals by electricity instead of hanging goes into operation next year. If so, it is very suggestive, in regard to the controversy we are discussing, that such an able electrician as Mr. Edison is satisfied that a direct current dynamo is all that is needed for that purpose without regard to the alleged greater effectiveness in this respect of the alternate current dynamos.

This dynamo did not belong to the Columbia College plant, but it was furnished by Mr. Edison for the occasion, as well as an alternate current dynamo. Both were removed after Mr. Brown finished his experiments, which, it appears, he continued privately for a few days after the lecture.

One of the dynamos used belonged to the college plant; it was an incandescent light dynamo, of which the capacity was stated by the engineer to be 125 amperes and 110 volts. This dynamo was employed to obtain the alternate currents, by using it to feed the magnets of a Siemens-Halske alternate current machine after the usual manner, as represented in the engraving, exhibited here, which shows the essentials of the arrangement used, only with this difference, that the field magnets of the Siemens alternating machine were supplied by the direct currents obtained from the much larger 125 ampere dynamo referred to, in place of the small one represented in the engraving, at the right hand side below.

The kind of apparatus which was used and the nature of their arrangement, for the production of the alternate current, makes it very unlikely that it would not produce a considerable current. Especially when we take into consideration that the current developed must represent some kind of equivalent for the horse power required. Firstly to drive the 125 ampere incandescent light dynamo, next, that required to drive the alternate current dynamo; the latter must have consumed considerable power, as the 125 ampere current was more than sufficient to saturate its great number of stationary electro-magnets. According to the statement of the engineer, the engine driving the 125 ampere by 110 volt dynamo was of 36 h. p., but as this dynamo furnished only 125 x 110, or 13,750 watts, its duty, theoretically considered, amounted to the consumption of 19 h. p., so it appears that not as much as 36 h. p. was consumed. If we make allowance for the ratio of useful effects of Edison's dynamos as determined at the Philadelphia electric exhibition to be 90 p. c., we will not be far from the truth if we assume that this dynamo consumed 21 h. p. In regard to the alternate current dynamo, we may arrive at an estimate by knowing the fact that the other steam engine which previously drove the direct current municipal 1200 x 15 or 18,000 Watt dynamo, consumed theoretically 24 h. p., but making again allowance for the 90 p. c. useful effect as before, we obtain nearly 27 h. p. As it appears that this very steam engine drove afterward the alternating current machine, with the same velocity and steam pressure, we obtain the total amount of 27 + 21, or 48 h. p. required for the generation of the alternating current. This corresponds to the production of 35.808 watts. Assuming a current strength of 30 amperes, it would give 1,193 volts, for 15 amperes 2,387 volts.

Of course, this is an exaggerated estimate, but sufficient to show the underestimate of the figures as given by Mr. Brown. In order to come to correct conclusions it would be necessary to measure, by means of indicator diagrams, the engine power utilized, and measure the currents obtained by proper instruments, properly used and conscientiously observed.

But in fact it is scarcely necessary to go into any calculation to make it evident that the alternating current obtained must have been double that of the direct current, when we consider that for the direct current one steam engine and one dynamo was used, while for the production of the alternating current two steam engines and two dynamos were employed.

One thing is certain, namely, that the dynamos used were not of such a defective quality as to warrant the

supposition that this would not be the case, and the acknowledged absence of proper measuring instruments for alternating currents, connected with the fact that the estimate of the current strength which was switched in the circuit applied, appear to have been based upon the same amount of rheostat resistances, as had been used for the direct current, makes it very probable that the voltage of the alternating current was twice as high, if not more, than estimated by Mr. Brown.

There was added on the lecture room table another important additional (however small) contrivance, for the right understanding and use of which I will have to make a short introductory explanation. I do this also because I have been especially requested to do so, by several parties who had become interested in the operation of this, to them, very novel device

I must ask pardon for bringing some elementary considerations before this learned body, but my apology is that this paper will be published and read by many who are not so well informed about electrical subjects, and whose ideas upon it, need some clearing up.

Every one who has handled faucets attached to pipes from which water can escape under pressure, will have noticed that when suddenly shutting off the water, a blow like that of a hammer is produced in the pipes. This is caused by the momentum of the water when in motion (often very improperly called inertia), and which shows itself every time this motion is arrested. On this peculiarity is based a contrivance in which, by the automatic alternate opening and closing of a valve, a small portion of the water discharged may be raised to a greater height than that of the original device which produced the pressure. This contrivance has been called a hydraulic ram, and by its help an increase of pressure may be obtained at the expense of a certain quantity of water.

Notwithstanding electricity is not a fluid like water, it behaves, however, also in this case, in a similar manner; at the moment a uniform electric current is suddenly interrupted, a current of greater electromotive force (more pressure) is developed in the conductor, and will show itself as a spark at the break of contact, and as a shock through the body when the hands have hold of the wires when the contact is broken. It is a very old observation, and one of the earliest reminiscences of my boyhood (about 1823), that the current of a column of volta of say 30 pairs of plates, scarcely perceptible when closing the circuit through the body, will give quite a sensible shock when breaking the circuit. Such currents have been called extra currents, and they are, of course, stronger in proportion to the strength of the original current, and still further increased by inductive influences when there are coils in the circuit.

As it may be desirable for special purposes to eliminate these currents, an apparatus has been invented, which operates like a very sensitive relay, and then leads these extra currents off, or shunts them into another channel after the manner of lightning protectors. Such an apparatus was on the table during the experiments with the dog, and appeared to be intended to protect the animal against the effect of these extra currents. I must confess not to see why this was done, except for the purpose to annul the most powerful and most dangerous items connected with the direct current. Therefore, I consider the addition of this contrivance improper if we wish to arrive at the truth in regard to the comparative danger of the alternate and direct currents, because in case of accidental exposure of person, there is rarely such a safeguard inclosed in the circuit, and the person struck by the current must submit to the extra current as well.

In order to arrive at the truth of the matter we must also, above all, be able to make definite statements about the voltage and the volume of current, based on precise measurements, which, in regard to the alternate currents, could not be furnished but was only guessed at.

Finally, as far as I can judge about the matter, guided by the present state of knowledge (especially in regard to some, in many respects, still unexplained peculiarities in the behavior of alternate currents), I should say that their true voltage must be quite high. They do not behave like currents of low voltage (say 300 or 400) as they can be, and practically are, conducted over much longer lines and thinner wires than is the case with the direct currents of say 1000 volts. This fact is acknowledged as well by the enemies as by the friends of the alternating current system. Experiments made with converters, especially with a new and very peculiar one of my own construction, appear also to show that there must be considerable voltage in the alternate currents so as to account for the generation of the enormous volume of current into which the electromotive force is converted; in other words, for the thousands of amperes obtained by the conversion of the volts of the primary current, and for which amperes there is no ammeter yet to measure them; but their volume shows itself in the capacity to perform operations requiring the highest temperatures, such as welding iron, fusing the most refractory substances, &c.

Surely no dynamo could be constructed directly generating a current of such volume as it would destroy itself by the heat of its own current; it is only by alternating current machines of high voltage, assisted by proper converters, that currents of such great volume and high caloric capacity can be obtained.

I am satisfied that the alternating current dynamo has a great future before it, not only for electric illumination, but also for motive power, metallurgical and probably even electrolytical operations.

After all, we must not lose sight of the main objects of this controversy, which is the comparative danger lurking in the two systems. Were it found by experience that actually, the danger of being killed is greater by the use of alternate currents, it does not make any difference if the voltage which does the killing is 300 or 1300.

When, however, we consider that statistics show that the loss of life by the direct current system is continually increasing in proportion that the system is extending, the probabilities appear to be that both systems will furnish their equal quota of victims, and the labor of comparing the relative danger of both systems, and especially the discussion about their comparative voltage, appears to become an idle occupation.

Those who favor the burial of all electric light wires underground out of sight, overlook the difficulty to keep them out of reach also; namely, at their connection with the overground lights. This is no doubt easier with the existing system of overhead wires when placed all out of reach, while the sufficiently protective insulated covering may as well be applied to such wire, as is the case with the underground lines.

The agitators who want legislative interference against the use of high tension dynamos, should be consistent, and if the protection of human life *is their real motive*, they should attempt to obtain also legislation against the manufacture and use of high tension dynamite, nitro-glycerine, and other similar explosives; also against the use of gasoline lamps, burners and stoves, all of which produce almost daily their quota of victims. Further, against horse and foot races, rowing and swimming matches, base and foot-ball games, athletic sports, etc. Each of these have from time to time produced more accidents and loss of life than is the case with the electric light currents, about which it appears to be the fashion to make a great fluster when occasionally a life is lost, while the killing of a base ball player or jockey, attracts scarcely any notice.

The opposition of the alarmists who predict terrible disasters from the introduction of alternate electric currents, reminds me forcibly of the predictions made less than one century ago, when the world was warned against the intro-

duction of illuminating gas and railroad trains. About gas it was prophesied that it would blow up cities, or destroy them by universal conflagrations, and that railroads would cause the indiscriminate and wholesale slaughter of the reckless individuals who dared to tempt Providence, by trying to travel with the enormous velocity of 20 miles an hour. But the gas and the railroads have come to stay, and so will the high tension currents. The progress of the world cannot be impeded and much less arrested by a few timid alarmists.

DISCUSSION.

Dr. Moses—That very interesting paper calls to our attention some experiments which were made at Columbia College. However, I would like to warn you, gentlemen, that those experiments were not made by the professors of Columbia College but by a set of self-constituted investigators, who have tried to frighten the public, and by holding up a terror before them to scare them into a certain course. I think that one of the most beautiful passages I ever read was in that novel of Bulwer's, where he describes the perfect peace and calmness prevailing at Pompeii before the eruption and destruction of the city. We have been sitting here as a sort of mutual admiration society, taking in all the compliments, well meant and many of them true, of so wise a man as Mayor Hewitt. But, gentlemen, something has happened to-day which I think ought to be called to your attention, so as to awaken you from your lethargy, and I will read a passage from a letter in which a note of attack is sounded, which I think we ought to meet with serried ranks. This is a letter from Ex-Governor Cornell to Mayor Hewitt. I quote it as printed in one of the daily papers, and I am told it is the entire letter, with the exception of five unimportant lines :—

"The disposition of electrical wires in such manner as to abate their dangerous qualities, and at the same time to preserve their useful features, is a question demanding serious thought and urgent remedy. It has long vainly sought solution, and you are the man who can apply the true and only available corrective. The only remedy now practicable for removing the danger of high tension circuits, which presently menace the life and property of our citizens, is to absolutely prohibit their use within the city; the strong arm of the state by legislative enactment and honest executive administration of such law positively prohibiting the use of wires bearing the high tension circuits will give us safety. Nothing else can so quickly and surely accomplish it. Will you help us to this result?"

The President—I would like to know if Ex-Governor Cornell writes that letter as an expert or as a representative of the Western Union Telegraph Co. or some other interest.

Dr. Moses—We all know that Ex-Governor Cornell is largely interested in the Western Union. We also know his ability and his great influence, and when such a man speaks we must listen and reply. Gentlemen, I have prepared a set of resolutions that I think this association ought to promulgate for their own safety, recollecting the fable in Æsop where the bulls, when they kept together, could keep off the lion, but the instant they separated they were devoured by him. The effort is made to destroy one of the important interests which it is the duty of this association to foster. I call your attention to it and warn you. Gentlemen, this is the resolution :

"*Whereas*, The National Electric Light Association view with some uneasiness the persistent efforts of rival interests to educate the public to distrust of high potential electric currents ;

"*And whereas*, They would protest with all energy against recent efforts to pit against each other the continuous and alternate current systems of electrical distribution, which efforts had as their covert purpose the destruction of the harmony of action now existing between them ;

"*And whereas*, This association, for mutual protection, recognize distinctly the danger of unfair legislation, such as has destroyed the electric light interests of Great Britain ;

"*Therefore, be it resolved*, That the National Electric Light Association emphatically declare that it is beyond a doubt possible to produce and distribute high tension currents for public use without any more danger or difficulty than attends the distribution of gas and water in our dwellings.

"*And further be it resolved*, That they would impress all legislators with the fact that success in the electric light and power business is based chiefly upon economy in the size of the distributing conductors, and that to utilize this fact high tension current were adopted in the first stages of development of electric lighting, and have been used ever since, and will continue to be used ; and further,

"*Be it resolved*, That it is our conviction that there is no difference in the dangers attending the use of continuous or alternating currents, and that both may be so transformed before being used as to render them a perfectly harmless and practical means of distributing electric power for use in cities."

The adoption of the resolutions was moved and seconded.

Mr. Steuart—This is not a time when it is desirable to harp upon a political issue; but it seems that the policy that is prevalent throughout the country is one that should guide us in adopting these resolutions. The protection of American industries is one of the things which is exciting the public mind. The protection of one of those industries is one of the things for which this organization was formed, and one of its greatest elements of usefulness. I can speak from the observation of my friends in England, who have told me of the very great depreciation of the electric light business which has been the result of adverse legislation in that country towards electric lighting. The gas interests there are very powerful, and they have succeeded in so influencing Parliament as to secure the passage of laws, which for the past ten years have crippled the industry which has grown to such proportions in this country, and I hope that this association will put itself upon record by adopting these resolutions, as opposing any such policy, and as stating to the world our view of the subject, as those who have had the most experience, and the most practical experience, in handling this class of business.

Mr. T. Carpenter Smith—There is one feature of the legislative interference with the electric light business in Great Britain which I think deserves our very serious consideration. We have been reading, I have no doubt all of us, in English journals descriptions of English installations, and a good many criticisms have been passed on the other side of the waters about the flimsy method of installation which prevailed in this country. Now, the fact that there has been very little work done in England, is very clearly to be attributed to the adverse legislation, and as a consequence of that the few installations that are being operated to-day are being operated in a most reckless manner, such as would not be tolerated in this country. As an instance of that I would mention the fact stated by Mr. McKenzie, I think at the meeting of telegraphic engineers there, in reference to the system in the Grosvenor Gallery, that he had as many as six buildings cut out by the grounding of wires on the gas pipe fixtures, and he recommended that the chandeliers, if they had to be used for electric lighting, should be insulated in that way. I don't know how many years it is since we were ordered to put in insulating joints on all lines; but that in 1888 is the condition of the electric light in England, and it is a striking commentary on the effect of adverse legislation. The more the electric light is used the more precautions will be taken with it; for the public are your customers, and unless you protect them you will ruin your own interests.

Mr. Lynch here read, for the information of such members as were not present at the time Mayor Hewitt delivered his address, that part of his Honor's remarks wherein he referred to the sensational articles appearing in the newspapers with respect to the dangerous character of electric light wires.

The resolutions proposed by Dr. Moses were then unanimously adopted.

Dr. G. A. Liebig, Jr., then read the following paper :—

SOME METHODS OF ELECTRICAL MEASUREMENT.

BY G. A. LIEBIG, JR., PH. D.

AMONG the requirements of modern electrical engineering and the usual practical work in electricity is the ability to make accurate and reliable measurements of current, of potential, of capacity, etc. And with the growth of practical electricity itself goes hand in hand the increasing necessity of instruments of precision and standard apparatus with which the various appliances in every-day use may from time to time be compared.

It may not be out of place, therefore, to give a brief account of some methods of measurement and comparison, many of which have been thoroughly tested, and one or two of which are believed to be new and more reliable than the methods hitherto applied. Let us discuss first of all the best manner of measuring *currents*.

Current determinations may very conveniently be divided into two groups, *i. e.*, the measurement of heavy currents, and the measurement of small currents. Of the latter very little need be said, as the best method undoubtedly depends upon the use of an electro-dynamometer, and the most suitable form of such an instrument is that of the British Association, the well-known Weber electro-dynamometer, which has been thoroughly explained and mathematically treated at length by Maxwell. With two or more electro-dynamometers of this kind, currents, ranging from a few mille-amperes, to 10 or 25 amperes, can readily be measured with an accuracy of one part in two or three thousand. Currents greater than this must be determined by some other arrangement, since a dynamometer capable of accurately measuring very heavy currents would have to be of

massive proportions and of correspondingly increased cost. An instrument at the Johns Hopkins University, which is intended to measure currents up to 15 amperes, has fixed coils one meter in diameter.

For heavy currents it has been found advisable to apply the method of "fixed resistances," a method which has been used and successively improved in several electrical exhibitions in this country and abroad, and the range of which is practically unlimited. In this method the current to be measured traverses several heavy german-silver bars which have been hard soldered to a pair of very large copper blocks to which are fastened, in the same way, the terminals of the galvanometer leads. The bars and end blocks are immersed in a tank of refined petroleum, and their temperature, by stirring constantly the oil, can be determined to a few hundredths of a degree. To use this apparatus a known current, measured by an electro-dynamometer, is sent through the fixed resistance, and the potential at the ends determined by the galvanometer joined at these points. The deflection of the latter corresponding to any other current, gives us at once a measure of the current. In practice a resistance box is placed in circuit with the potential galvanometer, and the resistances always adjusted until approximately the same deflection is obtained. By doing this we render ourselves independent of the assumption that the angular deviation of the galvanometer needle is proportional to the current, except for exceedingly small differences. It is to be noticed, however, that the calibrating current is measured by an electro-dynamometer, and not by a galvanometer, the reason being that the former is independent of the value of H (the earth's horizontal component), whereas any error in the determination of H appears directly in the galvanometer constant.

During the measurements the oil in the tank is constantly stirred and its temperature noted. As a matter of fact this is found to change but little even with currents of 200 amperes or more. Calling R° the resistance of the german-silver bars at 0° C; β, its temperature co-efficient; T^1 and T^2, temperatures of the same corresponding to currents C^1 and C^2; D^1 and D^2, r^1 and r^2, and t^1 and t^2, the deflections of galvanometer, adjusted resistances, and their temperatures, corresponding to current C^1 and C^2, we have

$$C^2 = C_1 \frac{D^2 (1 + \alpha\, t^2)\ \surd^2 .\ R^\circ (1 + \beta\ T^1)}{D^1 (1 + \alpha\, t^1)\ \surd .\ R^\circ (1 + \beta\ T^2)}$$

α being the temperature co-efficient of the resistance box. The terms relating to changes of the resistance R°, *i. e.*, of the german-silver bars, can generally be neglected.

POTENTIAL MEASUREMENTS

can be made in exactly the same general manner, the "fixed resistance" used for this purpose being, however, very much higher. A known current is passed through the german-silver reel, forming the fixed resistance, and the deflection of the galvanometer, joined to its ends, is noted. A resistance box in circuit with the galvanometer enables us to reduce this deflection to a convenient angle. Care must be taken that the current used for calibrating the galvanometer be so small as to heat the fixed resistance as little as possible. After the calibration is completed, the galvanometer is joined to points whose electromotive force we wish to measure, and the resistance box adjusted until the same deflection as before is secured. We have then, an expression for the potential, of exactly the same form as the one given before. For very high potentials the method is inapplicable, and recourse must be had to an absolute electrometer of the kind first described by Sir Wm. Thomson. In this instrument, fully explained in Thomson's papers, the difference of potential between two points is measured by the attraction between two discs electrified to the same difference of potential, one of them being balanced by a series of weights, the other being fixed. With such an instrument electromotive forces varying from 1,000 volts to over 100,000 volts can easily be measured, and it thus offers an excellent means of comparison with electrostatic voltmeters, etc.

There is perhaps no better way of measuring *resistances* than by the employment of some accurate and sensitive form of Wheatstone bridge. The only difficulty encountered in such measurements is the exact determination of the temperature of the various resistance coils and standards in use during the work. It has been found absolutely necessary to immerse all the measuring coils in liquid during the use of the apparatus, and to allow them to remain in a room whose temperature is almost constant several hours before any measurements are made. Even thin glass tubes, containing mercury and surrounded on all sides with cracked ice, have been found to require at least five or six hours for their temperature to fall to zero.

The efficiency of dynamos and motors can be determined with all necessary accuracy by means of any one of several dynamometers of distinct types, and now well known, and the subject is one which presents no difficulty whatever until the attempt is made to measure the efficiency of very small machines; that is, machines of one horse-power and less. In these cases it has become necessary to devise a way of measuring which shall greatly reduce errors ordinarily encountered. The difficulty generally presented is that the dynamometer itself absorbs in friction so much energy that the loss thus occasioned amounts to a large proportion of the total activity of the machine under examination. The cradle dynamometer is perhaps free from this objection, but it must be rejected on account of the uncertain but large errors introduced by slight errors of centering. Hopkinson's method might be employed, were it not that it requires two machines to experiment upon; an obstacle which in most cases would be a serious one. A method which appears to be devoid of the objections just enumerated is a modified calorimetric method. To employ this the motor or dynamo, as the case may be, is surrounded by an air-tight water jacket through which circulates a stream of water at a uniform temperature. The dynamo is allowed to run under a given load until all the effects of heating have become constant; this includes the heating resulting from mechanical friction, and from the current itself. After this the flow of water is determined, its temperature carefully noted, and from these data the losses occurring in the motor are at once deducible. There appears to be nothing in the way of making the method universally applicable to small machines, and the indications are that its adoption would lead to very accurate results. This method was first proposed by Dr. Duncan as a means of measuring the efficiency of alternating current converters.

Several methods of determining the magnetic qualities of iron and steel have been published. They all depend upon the measurement by a ballistic galvanometer of the induction through a coil wound about the specimen to be tested, either when the coil is moved, the current reversed, or reduced to zero. These methods offer no difficulty, and a ballistic galvanometer can easily be calibrated in absolute measure by the use of an earth inductor or even a coil of wire of a few turns, its constants having been determined by measurement and simple calculation.

Dr. Moses—Would Dr. Liebig be so kind as to explain to us how in the measurement of small machines the difficulties developed themselves?

Dr. Liebig—The difficulty we had was that the dynamometer used required so much power to move. The dynamometer that is best fitted for that work is perhaps the Taten dynamometer; but it cannot be very well made on a very small scale, and it absorbs something like half to three-quarters of a horse-power to run it; so if you want to measure the efficiency of a one horse motor you have very little to go on.

Dr. Moses—Has Dr. Liebig determined the relative losses of direct and alternating motors?

Dr. Liebig—I have not as yet taken up that subject.

REPORT ON PATENT LEGISLATION.

Mr. Arthur Steuart, chairman, committee on patent legislation, then reported as follows:—Do not be frightened by this volume

of matter that I have here. I am not going to read it all. I only brought it for distribution. Six months ago, at the Pittsburgh convention, the committee on patent legislation was instructed to prepare two bills for introduction into Congress, one of them for the creation and organization of a Court of Patent Appeals to hear appeals in all patent cases coming from the circuits and from the patent office, for the purpose of shortening the final determination of causes and sending them to the Supreme Court directly, and also for the purpose of putting over the two branches of the government that has to do with patents, namely the Circuit Courts and the Patent Office, the same tribunals, thereby giving a harmonizing influence and creating a degree of harmony between them that does not now exist. We are all conscious of the confusions and we are all conscious of the difficulties, and it was determined that this was the best method by which harmony in the law and practice could be accomplished. For the purpose of formulating a bill that would be satisfactory, for the creation of such a court, your committee proceeded to correspond with every member of the association and everybody in this country who was found interested or from whom they thought they could get information, and I can say to you that the volume of that correspondence has been very great. As a result of the three months' work, the bill which I have in my hand and which I will not read in detail but simply call your attention to was finally determined upon and it has been submitted for consideration to the Supreme Court of the United States—that august body for which as a lawyer probably I feel greater respect and veneration than you do as laymen ; but it is certainly the most august and dignified tribunal in the world, and one for which we cannot have too much regard. I may say that I feel somewhat gratified when I can report to you that this bill which has been submitted to Congress is the first one within the recollection of any one with whom I have spoken which has received the public endorsement of that great and dignified court. There is printed in this pamphlet, and I will read it to you, a letter from the present acting chief-justice of that court, endorsing the measures. The Hon. Samuel F. Miller, the actual chief-justice at the time this letter was written, says :—

My Dear Sir :—It gives me pleasure to say that, after going over the Bill of the H. of R. No. 9,084, to establish a Court of Patent Appeals, and making a few suggestions which you accepted, I approve of the bill entirely. It will do much to relieve the over-burdened docket of our Supreme Court in a direction where it can best be done.

Although the Bill has been submitted to no distinct vote of the members of the Court, it has been considered by them all, and I feel sure that I express their concurrent opinion when I say that they all desire the passage of the Bill, and will be much gratified if it shall become a law.

I am very truly yours,
SAMUEL F. MILLER.

There is also a letter here from Mr. Justice Bradley, and one of endorsement from the late honored chief-justice.

The following letter from the Hon. Commissioner of Patents is printed in this pamphlet :—

Dear Sir :—I have considered the Bill, H. of R. No. 9,084, with amendments suggested before sub-committee of judiciary committee of the House, and am convinced that it meets the urgent requirements of the present situation. It will tend directly and immediately to relieve the Supreme Court of its enormously overgrown docket, and to abolish the delays in the administration of law which now almost amount to a denial of justice. The patent laws in their application must be applied by expert tribunals. The patent office is an expert in the arts. It is required to be such, not only by the nature of its duties, but by the principles of its organization. It is impossible that judicial tribunals can properly and safely revise and review its work, and adjudge the rights of the public and of individuals arising from its operations, without possessing an element of the knowledge and familiarity of the expert that lies at the foundation of the whole system.

I sincerely trust Congress can be induced to give the subject the consideration it is worthy of.

Yours very truly,
BENTON J. HALL,
Commissioner of Patents.

The matter was submitted for consideration to the bar. In Washington there is an organization which is formed for the purpose of fostering this measure, the Patent Bar Association. The president of that association, speaking for that organization and for the great mass of lawyers in that and other cities, says :—

"The Patent Bar Association of the District of Columbia is strongly in favor of a Court of Patent Appeals, such as is proposed by Bill H. of R. 9,084. We are clearly of the opinion that such a court would be of vast importance.

"First. By securing a far more uniform practice in the granting of patents, by which there would be less invalid patents granted, and the capital invested in patents and business enterprises based upon patents would be rendered more secure.

"Second. It would lessen litigation, and, what is equally, if not more important, it would enable patent cases to be decided in much less time.

"Third : It would relieve the Supreme Court, for very few cases would ever go beyond the proposed court.

"Fourth. It would put an end to the conflicting decisions which is one of the great troubles of the day."

W. C. DODGE,
President Patent Bar Association.

The bill contemplates the creation of a court of five judges, who shall hold their court in the City of Washington, and shall sit as long as is necessary for the completion of the work required of them. That court shall have special jurisdiction in all cases involving patents, trade marks and copyrights, for they are kindred subjects and should go to the same courts, on appeal from the Circuit Court of the United States, and also of cases involving the same questions on appeal from the commissioner of patents. The bill provides, on the suggestion of members of the Supreme Court, that this court shall make a finding of fact in all cases, that they shall take all the testimony in the case, and formulate from it a statement of facts which shall be the basis of all appeals to the Supreme Court of the United States. Now, we all know that the questions in controversy in a patent case are as a rule questions of fact. In nine cases out of ten a decision of the facts decides the case, and when this court makes a finding of fact there will not be one case in ten that will leave a bald question of law open to be determined by the Supreme Court. This will probably operate to constitute this court in the majority of cases a court of last resort in patent cases, and we may hope that after trying a case in the Circuit Court, or trying it before the commissioner of patents, we may in six months get a final determination of the case in such a court as this instead of waiting, as is the present rule, three or four years for the determination of a matter in the Supreme Court, with that much loss in the use of the patent.

This bill was introduced into Congress in April—the second of April—and was immediately referred to the judiciary committee of the House. It was referred to the patent committee of the Senate. The judiciary committee of the House has been the field of our labor since that time, and I fear that the members of that committee have begun to think that I have gone mad on this subject ; but any of you who have had experience with the procurement of legislation from Congress have found that the most persistent, constant, untiring effort is necessary in order to get an action from any of the committees. Mr. Hall, the commissioner of patents, Mr. Dodge, the president of the Patent Bar Association, the Hon. George Ticknor Curtis, whom I interested in the measure, other gentlemen from elsewhere, and myself, have been before that committee over and over and over again. We have been there twenty times if we have been there once. We have argued with them hour by hour, and I have here in my hands a batch of articles upon this subject, which have been prepared by very intimate men in various parts of the country—by Mr. Walker, of Hartford, Mr Mason, of Detroit, Mr. Dodge, of Washington, Mr. Curtis, of New York, all of them tending to demonstrate the necessity for the creation of such a court, and for the purpose of proving to the members of Congress the desirability of passing this measure. The day before I came away from home, I had the gratification of receiving a telegram from the chairman of the judiciary committee of the House, to say that after careful consideration, that committee had authorized him to report this committee to the House, with a recommendation for its immediate passage. (Applause.) I cannot say what the House will do with it, but I have heard few dissenting voices, and I am disposed to hope that, if the members of this association will aid me by individually approaching their members of Congress and indicating to them that it is very desirable that this bill shall pass, that it will become a law ; and I hope that when you go home, that every one of you will take the very first opportunity of either writing or going to Washington, seeing your members of Congress, and impressing upon them your personal desire that this thing shall go through. I may say that the House committee have cut down the court from 5 to 3 members, and have cut down the salary from $8,000 to $6,000. I am sorry for that. The burden cast upon this court by the transfer to it of cases now on the docket of the Supreme Court will be very heavy, and the mass of business thrown upon them will be very great. I do not think that three men can do the work. The Senate committee that has the matter in charge have assured me that when the bill comes to them, they will alter that, and instead of lowering, will increase the court to seven members and the salary to $9,000, so that we may hope to get good men. It is a question of policy as to whether it would be better for us to let the bill go through in the form in which it has been reported to the House, get the court, try the experiment, and if the justices are overburdened with their work, increase their number afterwards; or whether it would be better not to take our court at all until we can get what we want. My disposition is to let the bill pass through the Senate in the form in which it comes from the House; let the court be appointed, and let them try the work and see how they get along with it.

There is only one other word I will say in this connection. The work of this committee heretofore has cost within a few dollars of $700. When I undertook this work, I estimated the cost at $1,500. I said I thought it could be done within that figure. The members of the association have been very liberal and prompt in supplying the necessary money. Seven hundred odd dollars was subscribed and seven hundred of it has been spent. It remains with the members of the association to say whether this work shall go on or whether it shall stop. It is impossible to prosecute it without sufficient money for the conduct of correspondence, which has made it necessary to employ a clerk, and I may say that for the past six months, the work of this committee has occupied the whole time of one clerk in my office, every bit of it, and he a stenographer, and as much time as I could give to it in addition, the clerk simply, of course, doing the manual work.

It remains for the members of this association to continue this work or to stop it now. We want a little more money in it—a few hundred dollars, and we believe that the benefit of this measure to the members of the association will be so great, that whatever they may spend upon it, they will be well compensated for.

Mr. Foote—As I was one of the few at the last meeting of this association to give our friend Mr. Steuart a little encouragement in his work, I deem it a privilege now to express to him my personal thanks, and I hope the thanks of all the members present, for the work he has done. I think he has got it in excellent shape and that it should be carried forward.

With regard to the question he asks about having the bill passed as it is, without an increase of judges or salary, I think the principle recognized in all legislation is first get your commission, then give them power. On that principle, I would favor any action that would secure the court. Having secured that, if we find it inadequate to its work, it will be easy enough to increase their number, their compensation, and all necessaries to carry on the business.

Mr. Steuart—I failed to say one thing, which I think it right to say, and that is that the money which has been expended on the work of this committee, had been the voluntary contribution of individual members of the association, who have been sufficiently interested to come forward and supply the funds. I do not ask that any of the funds of the association be applied to this purpose. I am satisfied that if the work is continued and if the association feels interested in it and approve of the work as it has been done, that funds will be forthcoming from the individual members to carry it on.

Mr. Weeks—I move that the report of the committee be received and filed, and the committee continued; and in making that motion I want to say that I feel proud of our legal committee. I think they have accomplished a noble work, and I feel quite sure from what I have heard from members of Congress that they are on the way to success.

Mr. Garratt—seconded Mr. Weeks' motion.

Mr. Foote—I would suggest to the mover of that resolution, that he add to it that the treasurer of this association be authorized to open the subscription for a fund to carry on the work.

The President—That had better be made separate from the other motion. It introduces a money matter in connection with the adoption of the report. Before putting the motion for the adoption of the report and continuing the committee, I would like to say a few words. I took the pains to go down to Washington at Mr. Steuart's request to aid him as much as possible in the prosecution of this work before the committee; and no man, unless he has been through that kind of legislation, can appreciate the amount of hard work it takes to see the various members of the committee of a legislature or of Congress, the amount of time spent in hunting them up, the amount of time spent in trying to get a quorum; add to that the amount of labor that Mr. Steuart has performed in conducting all this correspondence, and in collecting data and the opinions of these learned gentlemen, and the endorsement which he has secured from the legal fraternity and the members of the Supreme Court itself—consider all that, and it is certainly something that deserves the thanks of the association. You know we restricted the committee in this way: We said we will give you the moral backing of the association to prosecute this work, but we will give you no money. Now that is a pretty easy thing to do. But, as he says, the individual members of the association have stepped forth and so far paid the expenses. It is gratifying to know that outside of ourselves, as an organization, the members feel such an interest in matters of this kind that they are willing voluntarily to come forward with sufficient funds.

The motion to thank and continue the committee unanimously carried.

Mr. Foote then offered a resolution that the treasurer of this association be authorized to open a subscription for a fund to defray the expenses of the work of this committee.

The resolution was adopted.

The President—Before going any further, gentlemen, I desire to refer to some statistics presented by Dr. Wheeler to our stenographer, in order that they may go upon the records and complete his paper. Some of it is the information asked for yesterday, in regard to the number of dead wires and dead poles, and so on, in the City of New York. (See page 435, for the tables of Dr. Wheeler.)

Mr. E. R. Weeks, of Kansas City, than read the following paper :—

ELECTRICAL EDUCATION.

BY EDWIN RUTHVEN WEEKS.

The signs of the times point to a growing interest in electrical education. In the rapid development of the applications of electricity, the demand for skilled workmen far exceeds the supply, and both employers and employés are beginning to realize that the men at hand must be assisted to a mental culture, whose lack is one of the drawbacks to perfect service.

In response to a few remarks made on this subject at the Boston convention, I have received so many letters of inquiry as to the ways and means of acquiring knowledge which will be of practical value to the workman, that it may be profitable to outline a plan that has proved its working value to employés of all grades of educational advancement, the greater number of whom, however, had previously had so little commerce with books as to be almost helpless before a small library.

When the full measure of the utility of electricity has been reached and when schools have had time to understand the needs of electrical engineering, the work of the college will afford all the preparation that theory can give. Already good courses in this line of investigation have been added to the curricula of many universities. With this branch of the subject we are not at present concerned. But it may be said in passing that the practical work in the factories, which is intended to supplement the college course, is not sufficient to make a man an electrical engineer. So great has been the demand for "expert" service, that many new fledged bachelors of science have been rushed through factories, and sent out to do work requiring *manual dexterity* and an *intimate practical knowledge* of the operation of apparatus under widely varying conditions. Before the student enters the factory he should have taken his degree, and should have spent at least a year at central station work where he may learn to use his hands and may become familiar with many varieties of trouble and gain an experience which will render the factory course of greater value to him. However, our immediate concern is, how to help the army of raw recruits, that the youth and rapid growth of our industry necessitates—to most quickly acquire an intelligent, practical, working knowledge of the service.

The mutual improvement society organized among the employés of the Kansas City Electric Light Co. has learned numerous lessons in regard to proper methods, useful books and the use of them, and in order to open the discussion on this phase of electrical education, I have consented to outline the work of that society. In 1885, the company provided a commodious reading room and a large audience room fitted with a library, paper files, black-boards, tables, writing materials, etc. Some half-dozen electrical papers and magazines are here on file and the library now contains over one hundred volumes. (See list.)

Twenty-five of these volumes, chosen with an eye to simplicity, served as a nucleus to which additions have from time to time been made. The selection of books for first use was an important work, as many texts are gotten up in a style and nomenclature, entirely beyond the taste and reading ability of the ordinary dynamo, lamp, and lineman. The officers of the company made it a point to talk with the men on various subjects treated in the periodicals and books, and to call attention to articles that might be helpful. Other things being equal, those who showed, in their conversation, that they had been studying, were first promoted. The librarian has kept a record of the books taken out, which shows that next to the unabridged dictionary, the one in greatest demand has

been "Electricity in the service of Man," by Dr. Alfred Ritter Von Urbanitzky. Almost every member of the society has read it and some, several times. Next in popularity stand "Elementary Lessons in Electricity and Magnetism," by Thompson, the works of Gordon, Holmes and Du Moncel on "Practical Electric Lighting," and "Electricity; Its Theory, Sources and Applications," by Sprague. Several copies of each of these works had finally to be provided to meet the frequent calls. Men in all branches of the service read them, and find that their perusal results in great benefit. A recent addition to the library, F. M. Kimball's "The Dynamo; How It is Made and How to Use It," whose simplicity and brevity will commend it to every workman, bids fair to become the most popular book with beginners. "Short Lectures to Electrical Artisans," by Fleming; "Elementary Treatise on Electric Batteries," by Niaudet; Hospitalier's "Domestic Electricity;" Brennan's Electricity and Its Discoverers;" Jeans' "Lives of Electricians;" "The Electric Motor and Its Applications," by Martin and Wetzler; "Electrical Measurement and the Galvanometer, by Lockwood; Day's "Electric Light Arithmetic;" "Dynamo Electric Machines," by Thompson; and Pray's "Twenty Years with the Indicator," are also favorite works.

The more purely theoretical treatises are taken out by few; but the number of their readers is gradually increasing. Among the more recent publications, there is one book deserving special mention. It is Mr. Hering's "Principles of Dynamo Electric Machines," which for the clearness, accuracy, and subject-matter should be in the hands of electrical readers of all classes.

The success of the reading room soon led to the organization of the Gramme Society, and the work of its members shows that the men are learning how to read. There was, at first, a little opposition to it among the men, some of whom objected to giving away the information which they had gained by hard knocks against experience. But this feeling has gradually died out, and all have come to realize that, in words of one of our linemen, "This is a case where one can give away his cake and eat it too." An additional inducement to membership was offered by establishing a relief fund in the society, to which each member subscribes at least twenty-five cents a month, the aggregate monthly subscription being doubled by the company. In case of sickness or disability of any member, he receives his *pro rata* share of the fund, and more should the society so decree. So that now, although the membership is not compulsory, most of the men in the service of the company have joined.

The meetings were formerly held on Sunday afternoon, but Tuesday evening was finally selected as a better time. The organization is of the simplest, and there is no membership fee. The officers are elected annually; and a committee, appointed by the chair, chooses the subjects and leaders of discussion under the advice of the general manager, who endeavors to so direct the whole work, that a reading of current electrical literature shall be necessary to the intelligent hearing of the various talks. Care is taken to assign each topic to those who have had the most practical experience in regard to it. Among the subjects already considered are, "A Talk on Magnets," "Early History and Sources of Electricity," "The New Light," "Technical Terms," "Electrical Units," "Ohm's Law," "Shunts," "The Arc Lamp," "The Incandescent Lamp," "Carbons," "Construction and Maintenance of Lines," "Danger from Shocks," "Grounds, Crosses, and Short Circuits," "Lubrication and the Proper Care of Journals," "Various Types of Dynamo Electric Machines," "The Edison and Thomson-Houston Machines; Their Construction and Proper Care," and "The Alternating-Current System." The discussions of some of these subjects required several meetings. In addition to the working topics, a biographical sketch of some noted scientist, especially an electrician, is given and is found to awaken a deeper interest in electrical study. The discussion of the subjects is both theoretical and practical, and the speakers have been led to a free use of the black-board for synopsis, diagrams, and illustrations.

The beginnings of the work were rather disheartening, and it required a great deal of enthusiasm and patience on the part of its inaugurators, to induce the men to take any useful part in the exercises. It was only by continual questionings and references to books and periodicals, by pointing out the advantage to be derived from the perusal of this or that article in this or that paper or book, the constant recognition of the good work of each speaker and the ignoring of the weak and useless, that the men were gradually encouraged to take hold of the subjects in a free and easy way, and to give up the cream of their experience without fear of losing it.

But the results have amply repaid all efforts; and the growing interest of the members, their anxiety for perfect equipment and above all their ready expression of the advantage which the necessary reading and the interchange of thought have been to them, are most gratifying proofs of the wisdom of the movement.

Those members of the society whose information lay chiefly in a practical direction, have added to that information and have gained a knowledge of some of the principles underlying our industry. They are thus deriving more pleasure from their work and are on the way to a higher and wider field of usefulness. Those whose information was mostly of a theoretical nature have clinched such information, and have acquired a more intimate knowledge of the apparatus used, and are thus better prepared to discharge the duties devolving upon them.

The benefits of this work to the company are evident in the improved condition of all parts of the service, and in the interest which the employés take in perfecting it—an interest which has grown out of the dawning perception that the company has at heart the good of its workmen, as well as the increase of its dividends.

LIST OF BOOKS IN THE LIBRARY OF THE GRAMME SOCIETY.

Alglave & Boulard.—The Electric Light; History, Production, etc.
American Electrical Directory.
Anderson.—Lightning Conductors.
Atkinson.—Static Electricity.
Ayrton.—Practical Electricity.
Benjamin.—Age of Electricity.
Blakesley.—Alternating Currents.
Bottone.—The Dynamo; How Made and How Used.
Braunt & Wahl.—Techno-Chemical Receipt Book.
Brennan.—Electricity and Its Discoverers.
Browne.—Fuel and Water.
Buel.—Safety Valves.
Colburn.—Steam Boiler Explosions.
Cooke.—The New Chemistry.
Cotterill.—Applied Mechanics.
Cumming.—Introduction to the Theory of Electricity.
Day.—Electrical and Magnetic Measurements.
Day.—Electric Light Arithmetic.
Deschanel.—Natural Philosophy.
Du Moncel.—Electric Lighting.
Du Moncel.—Electricity as a Motive Power.
Du Moncel.—Incandescent Electric Lights.
Du Moncel.—Electro-Magnets.
Dyer.—Induction Coils.
Everett.—Elementary Treatise on Natural Philosophy.
Faraday.—Experimental Researches in Electricity.
Fiske.—Electricity and Electrical Engineering.
Fleming.—Short Lectures to Electrical Artisans.
Gordon.—Physical Treatise on Electricity and Magnetism.
Gordon.—Practical Treatise on Electric Lighting.
Gordon.—School Electricity.
Haskins.—The Galvanometer.
Hering.—Principles of Dynamo-Electric Machines.
Holmes.—Practical Electric Lighting.
Hopkinson.—Dynamic Electricity.
Hospitalier.—Domestic Electricity.
Hospitalier.—Modern Applications of Electricity.
Jeans.—Lives of Electricians.
Jenkin.—Electricity and Magnetism.
Kapp.—Electric Transmission of Energy.
Kempe.—Hand-Book of Electrical Testing.
Kimball.—The Dynamo; How It is Made and How to Use It.

Lockwood.—Electrical Measurement and the Galvanometer.
Lockwood.—Electricity, Magnetism and the Electric Telegraph.
Lomnell.—Nature of Light.
Maier.—Arc and Glow Lamps.
Martin and Wetzler.—The Electric Motor.
Maxwell.—Electricity and Magnetism.
Monroe and Jamieson.—Pocket Book of Electrical Rules, and Tables.
Niaudet.—Elementary Treatise on Electric Batteries.
Nead.—Student's Text Book of Electricity.
Planté.—Storage of Electrical Energy.
Pray.—Twenty Years with the Indicator.
Prescott.—Bell's Electric Speaking Telephone.
Prescott.—Electricity and the Electric Telegraph.
Proceedings.—The Association of Edison Illuminating Companies.
Proceedings.—The National Electric Light Association.
Pynchon.—Chemical Physics.
Radau.—Wonders of Acoustics.
Rowan.—Boiler Incrustation and Corrosion.
Sawyer.—Electric Lighting by Incandescence.
Schilling.—The Present Condition of Electric Lighting.
Smith.—Work Measuring Machines.
Sprague.—Electricity: Theory, Sources and Applications.
Stewart.—The Conservation of Energy.
Swinburne.—Practical Electrical Units.
Thompson.—Dynamo-Electric Machines.
Thompson.—Dynamo-Electric Machinery.
Thompson.—Elementary Lessons in Electricity and Magnetism.
Transactions.—American Institute of Electrical Engineers.
Treglohan.—Magnetism.
Treglohan.—Static Electricity.
Tyndall.—Lessons in Electricity.
Urbanitzky.—Electricity in the Service of Man.
Watt.—Electro-Deposition of Gold, Silver, etc.
Webster.—Unabridged Dictionary.
Wentworth.—Practical Arithmetic.
Wentworth.—Complete Algebra.
Wentworth.—Plane and Solid Geometry.
Wheeler.—Trigonometry.
Wigan.—Electrician's Pocket Book.

DISCUSSION.

The President—You have before you for discussion this very able and practical paper of Mr. Weeks, describing a school for imparting practical knowledge, under the management of his company, guiding its men in such channels as to give them the most practical and useful knowledge.

Dr. Moses—I think Mr. Weeks has set a very good example to all companies. There is no relaxation to the hard working man equivalent to studying up why he works and how to ease his work. It is very necessary that the people who are employed in the lower positions should be better educated. They are apt to get into a perfunctory way of doing their duty. Many an important thing too is suggested by the man who is engaged in running the apparatus.

In an humble way I have been at work on something in the same province. I take pleasure in announcing to you that I am now trying to breed up for you a class of workmen who will take charge of many of the positions in the electric stations and who will be able to do a great deal of work for you and do it intelligently. Next year I hope to be able to tell you of some practical results from it. There is a school in this city with which I happen to be connected as director and vice-president, which has for four years been engaged in educating poor boys. We have now about 125 boys under tuition. I have tried to develop in that school a system by which those boys may become useful to us. I look upon the electrical business as the rising business of this country. All other businesses in which motive power is developed will gradually be absorbed by it, and the workmen necessary to be employed in that are very scarce and are becoming scarcer every day. We have been dependent on foreign importation largely for our supply of skilled workmen. They have somewhat banded themselves together, and it is very difficult for a native to get that education which we find many of our foreign workmen have. The object of this school is, as I say, to furnish young skilled apprentices, thoroughly educated in electrical methods and for electrical purposes. I hope next year—though we have some 25 or 30 of our boys at different electrical works doing very good work—I hope to be able to announce to you that the matter has taken such shape that you may look to them for a certain supply of capable employés.

I am very glad to see that Mr. Weeks, who seems to be a born educator himself, has directed his attention to it.

Mr. Foote—Mr. President, I consider this subject of education as the basis of our business. While here I have taken the pains to get every periodical I could find treating on the subject, intending to give them to our workmen.

A point that Mr. Weeks touched upon I have had a little experience in, and that is that some of the workmen do not like to give away what they know, what they have learned practically. About six weeks ago I had occasion to learn something. I addressed a letter of inquiry to the managers of 100 central stations located in every state in the United States. I have received to that letter of inquiry up to to-day 86 answers, and all of the answers have given me in the fullest detail which the writer possessed the ability to give, a full answer to the questions I asked. That experience gives me a good deal of faith to believe that the questions which the committee on insulation have formulated and sent out will produce a great deal of good in bringing in answers. It struck me while Mr. Weeks was reading his paper that possibly it might be well to institute some sort of a circulating library scheme among the local companies in the different localities having, say, a small fee for the use of the books; a fund could be raised by which any book published could be made available to any man who has the intelligence to read it.

Mr. Steuart—I have been deeply interested in this paper of Mr. Weeks, and also in the remarks of Dr. Moses upon this subject, and I would throw out for your consideration one suggestion: The greatest educational influence that has ever been brought to bear upon a community, the greatest influence for practical progress in the development of the arts has been the patent system of the United States. It has done more to make this business than any other one cause, and I would suggest to you, that the spirit of that system is that the government of this country exercises a paternal care over its citizens and extends to them the strength of its arm in protecting them in whatever new step forward they may make in the development of any branch of science or art. The result is, that every citizen of this country feels that what he may do, what he may create as a step forward in the arts becomes his property in the present state of our law, and that he may reap from it the benefit which he certainly deserves. There are some manufacturing organizations in this country that have tried the experiment, and have found it most successful, of constituting themselves a patriarchal government over their employés in the same spirit and under a somewhat similar system as that which exists under our patent law, and I would ask you to consider that suggestion that you put before your men a proposition that they shall exert their very best endeavors to improve the condition of your service, and that for every idea of improvement that they present they shall receive recognition. That recognition I feel satisfied will give you a quality of service that will pay you for its cost.

Mr. Lynch—I must say that I have been highly interested in the remarks of Mr. Weeks, Dr. Moses, and Mr. Steuart, and for the purpose of following up this very interesting topic I will offer the following resolution and suggest the appointment of a committee of three, Mr. Weeks to act as chairman, for the purpose of considering the advisability of communicating with and suggesting to all our scientific colleges that they should follow up a course of practical electric instruction.

The President—The resolution is that a committee of three, of which Mr. Weeks shall be chairman, be appointed to suggest and recommend to all our scientific colleges a course of practical electric lighting education.

Mr. Weeks—While I appreciate the compliment the gentlemen would pay me by constituting me chairman of that committee, I feel that there are so many drains upon my time and strength that I shall not be able to carry that matter on as it should be carried on, and, therefore, I would respectfully withdraw in favor of Dr. Moses.

The resolution was adopted.

The committee on the place of meeting and the nomination of an executive committee then reported as follows:—

"Your committee appointed to select a place for the next annual meeting of the Electric Light Association begs leave to report, that it recommends the City of Chicago for such place of meeting. So far as your committee has been able to learn there is a general sentiment in favor of holding this meeting in some Western city, and other Western cities have consented to waive their claims for the next meeting in favor of Chicago.

"As members of the executive committee for the ensuing year we recommend the following names: Chairman, B. E. Sunny, Chicago; S. A. Barton, Chicago; W. A. Kreidler, Chicago; O. A. Moses, New York; E. F. Peck, Brooklyn; J. F. Morrison, Baltimore; E. T. Lynch, Jr., New York; T. C. Smith, Philadelphia; F. Ridlon, Boston."

C. A. Brown, *Chairman.*
A. J. DeCamp,
H. D. Stanley,
Thos. Officer,
E. R. Weeks.

On motion of Mr. Lynch, the report of the committee was adopted, and a ballot for the election of an executive committee was unanimous for the gentlemen named in the report.

Mr. Steuart, chairman of the committee on the president's address, presented the following report:—

Mr. President and Gentlemen:—"I am instructed by the committee on the president's recommendations, of which I have the honor to be chairman, to make the following report: There is but one subject contained in these recommendations that has not already been disposed of by the convention, and that is the question of establishing a permanent office for the association.

"Ever since the organization of the association a need has been felt for some permanent officer who would be in a position to gather up all the threads of the association's work and bring them to a practical focus, collect and collate information needed by the members and not furnished by the reports of the convention, and have this information ready for the use of the members when needed. It has not heretofore been thought best to undertake this work, but your committee, after careful consideration, agree with the president in thinking that the time has come for the establishment of such an office.

"They also think that the officer proposed should be a person thoroughly familiar with the field of electric lighting and kindred subjects, and that his office should be located in the City of New York, and be furnished with such a collection of books and magazines as would enable him to keep himself abreast of the development of the science and the industry. The committee, therefore, recommend that a resolution be adopted by the convention to the effect that the association have a permanent location in the City of New York, and that the position of secretary and treasurer of the association be held by an expert electrical engineer, and they recommend that the president at once take steps to nominate a suitable person for this position, and select a suitable location in this city for a central office."

ARTHUR STEUART, *Chairman.*
EDWIN F. WEEKS,
A. F. MASON,
HENRY D. STANLEY.

The committee submitted the following resolution :—

"*Resolved*, That this association shall hereafter have a permanent office in the City of New York, which shall be in charge of an expert electrical engineer, who shall be the secretary and treasurer of the association, and that the president at once take steps to procure the services of such a person, and establish him in suitable quarters and with suitable facilities in this city."

Mr. Phelps moved the adoption of the report.

Dr. Moses—It seems to me that we ought to take into consideration the valuable service of the secretary, and before that resolution is offered I would propose a substitute for it, or at least an antecedent resolution, in which Mr. Harding's services shall be properly recognized by the association. If the stenographer will take the resolution down I will dictate it. As we have been faithfully served by Mr. Harding I think he should receive some recognition from us for that in the way of a vote of thanks and appreciation. I therefore move that the appreciative thanks of this association be tendered through the president to Mr. Harding, of Baltimore, for the zealous manner in which he has performed the functions of his office, the care that he has taken to have everything in the way of records properly prepared, and that we congratulate ourselves upon having had a secretary, our first salaried officer, so efficient a one as Mr. Harding.

Mr. Steuart—I am prepared to second that motion in the name of the committee.

The President—Will the chairman of the committee state if the committee has ascertained about what the expense of the proposed office in New York will be, and if the association, in their judgment, is able to meet it.

Mr. Steuart—The committee would only say that during the coming year the income of the association will be somewhere between $4,000 and $5,000. In view of that fact the committee thought that half of that sum might be expended for the purpose of maintaining this office.

The resolution of thanks to Mr. Harding was unanimously adopted by a rising vote.

The motion to receive the report of the committee and adopt the resolution proposed by the committee was carried.

The President—I have here a telegram—a somewhat peculiar telegram :

Cincinnati, O., 31.

President National Electric Light Association :—

"Have association select an expert to act with our committee on award for electrical appliances. Will inform you later when he will be needed."

L. C. GOODALL, *Chairman.*

Gentlemen what is your pleasure?

Mr. Foote—In explanation of that telegram I wish to say to the association that the commissioners of the centennial exhibition in Cincinnati have expended about $40,000 in electric lighting and other electrical display, and there are several private displays. They have some committees to examine this electrical work and make reports upon it. As we have no local talent of commanding influence the commissioners have thought proper to invite this association to nominate an expert to act with their committees so that the action taken or the judgment given would command the respect of the electrical fraternity, and in respect to that telegram, I move you, sir, that the president be authorized to appoint such an expert to co-operate with the commissioners of the exhibition.

Mr. Lynch—While deeply sensible of the compliment conveyed to us by the gentlemen in Cincinnati, I think we are going very much out of our province in sending a delegate there to determine upon the question upon who shall take priority as regards successful apparatus at Cincinnati. It is something we have never done heretofore.

No one seconding Mr. Foote's motion, the matter was dropped.

Mr. DeCamp—I beg to offer the following :—

"*Whereas*, The value of capital is determined by the profits realized thereon, and

"*Whereas*, The risk attending the business of electric lighting, make it preeminently necessary that its capital be surrounded with such safeguards as will protect it against illegitimate competition, and

"*Whereas*, The practice of parent companies of furnishing apparatus and capital for the establishment of plants in cities and towns where local capital has already been invested is a growing evil ; therefore be it

"*Resolved*, That this association denounce such practice as detrimental to a common interest, and recommend its members jointly and individually to suppress it even to the extent of discriminating against all systems which persist in such practice."

Mr. Weeks—I move the adoption of the resolution.

Mr. DeCamp—At the Baltimore meeting a resolution was passed and a committee appointed on this subject. There was a report made that the committee had found little or nothing to do. In the last year or two I have heard very little of the evil, but since I came to this convention one case has been specially named in which there is absolute evidence of all the facts. It simply comes to this : That a parent company will by any means it can, legitimately of course, invite local capital to establish plant, and you know that they only get that capital and establish those plants on representations as to the return of the capital invested. They succeed in doing that. No sooner is that done than they offer, probably indirectly, but nevertheless with the same effect to loan to city authorities and other companies who are ambitious, both material and money to compete for public lighting. What is the result? I hear of public lights being offered as low as 12½ and 15 cents per night. That is downright robbery on the part of parent companies. If they know anything at all they know that there is no apparatus that will produce light for that price, and I do not think any action this convention can take will be too severe on any such party.

Mr. Ridlon—In regard to the committee Mr. DeCamp refers to and the action that was taken at Baltimore, that committee did call on a parent company who thereupon acknowledged their error and promised not to repeat it. It has been repeated now and fully as flagrantly as it was done in the first place, and as Mr. DeCamp says it certainly deserves a censure from this association.

The resolution was adopted.

The President—The chair will appoint as a committee on education, so that there may be no trouble in regard to the chairmanship, Dr. Moses, Mr. Weeks, and Mr. Foote.

Mr. H. L. Lufkin then read the following paper.

A BASIS FROM WHICH TO CALCULATE CHARGES FOR ELECTRIC MOTOR SERVICE.

BY H. L. LUFKIN.

THE theoretical side of the electric motor question has been very ably presented to and discussed by this association, but thus far the practical side has been somewhat neglected.

It will be my purpose in this paper, if possible, to show that there is a general average controlling the use of machinery which it will be safe for electric light and power companies to follow in making their charges for motor service, rather than adopt an arbitrary price per horse-power regardless of the character of service required of the motor.

I have arranged what might be called a power curve, representing the approximate average actual service in electric motors in connection with the several classes of work represented in the list accompanying the diagram.

This curve is calculated on motors which are only of sufficient capacity in each case to carry the full load. If the motor should be larger than is necessary to drive the machinery, the percentage of actual service will, of course, drop below that shown in the diagram.

By adopting a basis of averages which shall be general among members of this association, the charges for a constant horse-power of current may vary with the circumstances of its first cost in each case, but the general classification of motor service may be a comparatively fixed rule. I am not prepared to say that this is the best plan to follow, but respectfully submit the following as a possible solution of the frequently asked question : "How shall we charge for electric motor service?"

EXHAUST FANS.

First on the list of power consumers is the exhaust fan, taking it in average use. There are, however, circumstances under which its use will be limited to as low as 70 or 75% of its contract hours of service. As for instance, in a dining-room it may be cut out except during meal hours, or entirely cut out on cool days. In places of this description, however, its contract use is usually limited to three or four months in the year, and other than electric power is, by circumstances of first cost and inconvenience, but a feeble competitor. The first four applications on the accompanying list, viz.: Exhaust fans, blowers, ceiling fans, and fan outfits are all more or less subject to the foregoing conditions; and, therefore, current supplied to motors for these purposes commands the maximum price per horse-power. One important feature in the installation of ceiling fans is the counter-shafting to the motor. In one recent case we had a complaint from a customer that the ½ h. p. motor sent him would not drive two ceiling fans, and that the motor must be defective, and should be returned for repairs. We immediately sent a representative to find the difficulty, which was found, as is usual in such cases, in the counter-shafting, or rather the want of it. The 3-inch pulley on the motor was connected to a 6-inch pulley on the line shafting. The rated speed of the motor was 2,000 revolutions, and had it been able to develop this speed, would have driven the line shaft 1,000 revolutions and the fans at a relative speed. To accomplish this would probably require a motor of 3 or 4 h. p. The line shafting driving ceiling fans usually runs about 75 revolutions. To give this speed on the line shaft with a rated speed of 2,000 on the 3-inch pulley of the motor would require a counter-shaft, with a 24-inch pulley belted to the motor. On this same counter-shaft should be a 5-inch pulley belted to a 15 or 16-inch pulley on the line shaft. Fully three-fourths of the trouble found in electric motors arises from improper shafting and belting. A ½ h. p. motor should drive the average make of 30-inch exhaust wheel, about 400 revolutions. Say then the speed of the motor is 2,000 and the pulley 3-inch, it would require a 15-inch pulley on the fan to do the work; a 36-inch wheel requires 1 h. p. to develop the same speed. If the motor speed is 1,800, the pulley 4-inch, it would require an 18-inch pulley on the fan to do the work. These are the most popular sizes of exhaust wheels.

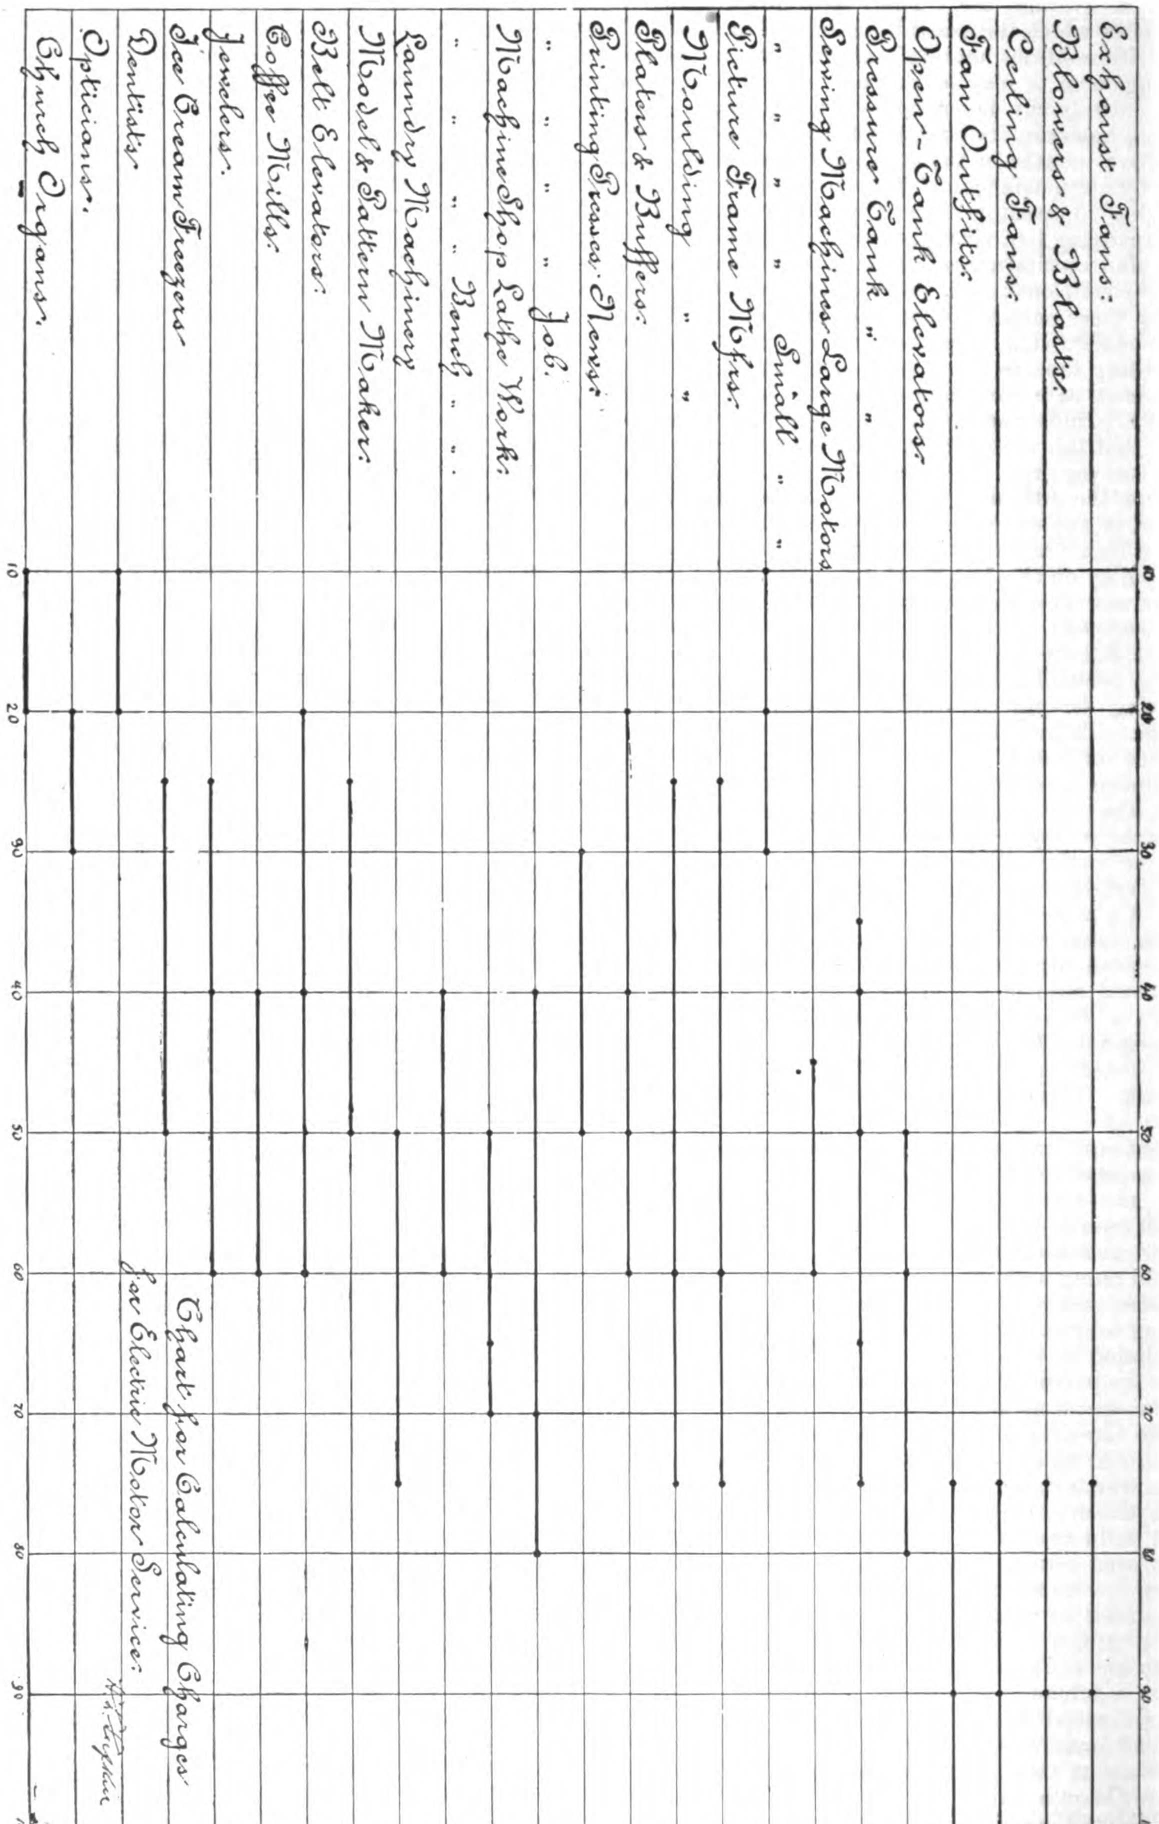
The next application on the list, open tank elevator pumps, commands the highest price for current per horse-power in the motor of any elevator application. The methods of operating the open tank hydraulic elevators in question are undoubtedly familiar to you all. Instead of the usual steam pump a power pump of some approved design is substituted and connected to the motor by suitable counter-shafting to give the required revolutions at the pump. The regulation of the motor in this case should be controlled by the position of water in the lower tank, as in the case of the steam pump. And in this connection let me suggest the necessity of great care both in installation and insulation. On all installations in basements and cellars or elsewhere, where there is the slightest tendency to dampness, raise the motor off the floor on a suitable frame or stand, and build around it on all sides of possible approach a low platform, using glass insulators as legs or standards to support it. So arrange this that the motor or its connections cannot be reached except when standing on this insulated platform, and the liability to a shock will be reduced to the difference of potential between the terminals of the machine. To return to the subject. Let us take for an illustration an elevator using 120 gals. of water per trip, and consuming one minute in making its entire up trip, or about two per round trip. The lower tank or water supply is on a level with the pump. The upper tank is 70 feet above the pump, and in the piping to the upper tank are five elbows. For each elbow add two feet to the elevation, or an approximate total elevation of 80 ft. × 120 gals. gives us 9,600 foot gals. This amount would be required every two minutes if the elevator was in absolutely constant operation, or 4,800 foot gals. per minute × 8½ gives us 40,800 foot pounds. This we must at least double to allow for friction in pump, shafting, etc., making 81,600 foot pounds, or about 2½ say 3 h. p., required in the motor.

This class of elevator is confined almost entirely to passenger use, therefore the service required of the motor is much more constant, and the margin between the horse-power hours contracted for, and the horse-power hours of actual service much smaller than in any other elevator use, excepting possibly the service in connection with pressure tank elevators in the more popular office buildings. In this case we have a maximum average use of 80 per cent., and instances such as the hotels, small office buildings, etc. where the service will not exceed 60 per cent. of the contract horse, power hours. In order, however, that the electric light company shall derive the greatest benefit from this inconstant service, the installation and wiring should be the best, and only the most approved and economical apparatus employed.

The next application on our list, pressure tank pumps in connection with elevators, represents a somewhat smaller percentage of horse-power hours of actual service in the motor, as compared with the possible horse-power hours, than in the case of an open tank pump. In case of the pressure tank the water reserve is usually limited, and the motor therefore must be equal to the continuous operation of the elevator at maximum load. Taking this fact into consideration, and the circumstances of elevator use being about the same in this case as in case of the open tank elevator, we have a greater ratio of difference between the possible or contract horse-power hours in the motor and the horse-power hours of actual service, the maximum average use being about 70 to 75 per cent., and the minimum as low as 35 to 40 per cent., depending of course on the character of building in which the elevator is employed or the character of service. In calculating the size of motor required on an elevator of this description a very convenient fact to remember is, that every pound of pressure per square inch is equivalent to lifting water about 23 feet, or about 230 feet per 100 pounds pressure. By reducing the required pressure to a relative lift in feet, and knowing the amount of water required by the elevator per minute, the motor calculation becomes the same as in case of the open tank elevator, the same allowances being made for friction, etc., as in the first case. The regulation of the motor in this case should be accomplished by the conditions of pressure in the pressure tank, as is the case with a steam pump employed in this service.

The next application of importance on the list is sewing-machines. In the tests I have been able to make on this class of work I have obtained some singular results. One item of importance is the fact that the single thread machines, which are lightest running, consume the most power in operating. Paradoxical as this may seem it is easily explained. As a rule this class of machine is used on light work such as shirts, ladies' underwear, etc., and operated at a higher speed than any other class of machine. At equal speed the volts consumed on a single thread machine, as compared with a shuttle machine, are about as two to three. In average commercial use, however, the positions are reversed, and the ratio of volts consumed in the single thread, as compared with the shuttle machine, is about as five to three. To double the speed on a sewing machine requires about two and a half times the power. The difference in volts consumed on the different makes of sewing machines is so small that we may disregard it entirely, as well as the character of work done by the machine, for the heavier the work the slower the speed, and more frequent and longer stops on the machine, thus keeping the average volts per operator about constant in all cases. This leaves

the speed in stitches per minute at the sewing machine the factor from which we must calculate the power required in



a sewing machine plant. To illustrate this I will give you the record of two cases, which are about the average.

Case No. 1 is a shop in which are 30 sewing machines, connected to a 2 h. p. motor. At the time the tests were made there were but twenty operators at work leaving ten idle machines, the entire shafting, however

being in operation. The class of goods manufactured in this shop is a cheap grade of cotton and wool trousers, rather heavy goods to sew. A voltmeter across the terminals of the motor gave the following readings, with the current at 9 amperes. Minimum, 90 volts; maximum, 148 volts; average, 119; which gives us a minimum average per operator of 4.5 volts, and a maximum average of 7.4 volts, or a general average of 5.9 volts per operator. This motor was driving the shafting for 30 machines, and as the average operators employed the year round will not exceed 75 per cent. of the shop capacity, it will, I think, be entirely fair to estimate the average volts per machine rather than per operator, as the user of the motor has contracted for power sufficient to drive his entire plant. In this case then we have a minimum average of three volts per machine, and a maximum of 4.9 volts, or a general average of say four volts per machine. A 2 h. p. motor of 82 per cent. efficiency, with 9 amperes of current, will require about 200 volts to develop two actual horse-power. Two hundred volts therefore is what the electric light company contracts to deliver, while in reality they deliver only 129 volts, or 60 per cent., or a minimum average of 90 volts, or 45 per cent. of the power contracted for. These machines were making about 1,200 stitches per minute, an average of four volts per 100 stitches.

Case No. 2 is a shop in which there are 32 machines, running at about 1,200 stitches, each being supplied with an individual motor of $\frac{1}{8}$ h. p. capacity, and the class of goods manufactured being men's summer clothing, such as white duck vests, flannel coats, and vests, etc., the duck from which these vests are made being about as hard work on a sewing machine as can be found. In this shop were 24 operators at work. The maximum volts in this case were 116, and the minimum 40, a general average of but 78 volts, or about $2\frac{1}{2}$ volts per machine, with four more operators than in the first case, in which we had an average of 119 volts. This shop has been paying the electric light company $32 per month for more than a year, which is the price the same company charge for current for a 4 h. p. motor, approximately 400 volts, which the company contracts to deliver. This gives us a minimum average use of but 10 per cent., and a maximum of 29 per cent, with a general average of $19\frac{1}{2}$ per cent. In other words the company is saving in this shop the price of a $\frac{1}{8}$ h. p. motor each month, besides making a profit on the volts actually delivered. On a contract for three years the electric light company would be money in pocket if they would present the customer with 30 small motors, charging him $1 per month per motor for current rather than let him buy a 2 h. p. motor to operate the same machines with the necessary shafting at a charge of $18 per month for current. Taking this average, in case No. 2, of $2\frac{1}{2}$ volts per machine, from a 50-light machine we could run not less than 900 sewing machines, or about 18 to the arc lamp. At $1 per month per machine an income of $900 per month would be derived from a 50-light machine without any lamp expenses such as carbons, repairs on lamps, globes, etc. On the average, in case No. 1, of 4 volts per machine, we could operate but about 562, say 600 machines. Divided up in shops of 30 machines, and a 2 h. p. motor to each shop, we would have 20 2 h. p. motors. At a charge of $18 per month each we would have an earning capacity of but $360 per month from the same 50-light machine.

This is but one page from the thus far unwritten history of the much maligned small motor. Still the question is frequently asked, "Can we sell current for $1 per month for a small motor driving a sewing machine and make a profit?" As a matter of fact 50c. per month for small motors driving sewing machines yields a better profit to the company supplying the current than $10 per month per horse-power in large motors to drive the same machines; besides the immense advantage which the small motors possess of keeping the circuit in much better balance, the fluctuations due to the stopping and starting of large motors being at times a serious matter. One electric light company making rather a specialty of these small machines, rent the motor and supply the current for $1.25 per month per sewing machine, and report that at this price the motor service pays them a better percentage of profit than their lamps. This company have some 200 small motors on their circuits.

A more striking illustration of the advantages to the electric light company in the sub-division of power into the smallest possible units it would be hard to find. There is a difference in efficiency of from 15 to 20 per cent. in these two sizes of motors, but this difference is fully lost to the large motor in driving the shafting, and the small motor still has the advantage of being out of circuit entirely when the machine it is driving is stopped. There is scarcely a manufacturing industry which does not possess its busy and dull seasons. This means that in no industry will over 75 per cent. of the machines or machinery employed be in average operation. The shafting in these shops must be kept in operation the entire year, often for less than 50 per cent. of the machinery. Sub-divide these same shops into as many small units as possible, and the current necessary to operate the shafting for this idle machinery will be saved, besides the saving from frequent stops while the machinery is in active use.

To return again to the list, the next two applications, picture frame manufacturers and moulding manufacturers, are very similar. Their busy seasons, as a rule, are in the spring and fall, and also follow closely any activity in house building. In the case of the larger manufacturers in this line a maximum average of 75 per cent. will possibly be reached but probably never exceeded. In the case, however, of the picture dealer who has a small shop, in which he makes picture frames and mouldings to order, the actual service of the motor will fall as low as 25 or 30 per cent. of its contract hours, one case in our experience the actual service having reached this low average. A fair general average in this class of work would be about 60 per cent.

The next application, nickel and silver platers and buffers, are good contract customers as a rule. One case in our experience showing but an average use of 20 per cent. of the contract horse-power hours. This, however, is probably an exceptional case, and as near as we can estimate on this class of work, the actual motor service will not exceed, in any case, 60 per cent. of the contract hours. A fair average being probably 45 or 50 per cent.

The next two applications, printing presses on news and job work, are probably met with more frequently than any other. On exclusively news work the instances where the motor is in service more than three or four hours is rare. It is, however, usual in news offices to find two or more job presses. If the newspaper printed happens to be a morning paper, the hours of news work are usually between twelve midnight and four o'clock in the morning, the job work being done through the day. I have in mind a case of this description. In the shop is one cylinder press and three job presses connected to a 2 h. p. motor. This motor is on an incandescent circuit of 110 volts. To develop its rated power at 110 volts would require about 16 amperes in the motor. An ampere meter in series with the motor, while running off the morning paper, with only the cylinder press in operation, stood at 12 amperes. For three hours this load was practically constant, when it was thrown off entirely. This gave on the night service but 30 per cent. of the contract hours. This motor required 5 amperes to drive the shafting, and but 8 amperes or 1 h. p. to drive the three job presses with the cylinder press off. Here then is but a 50 per cent. use if the presses be used constantly; there are, however, many days when they are comparatively idle; 30 to 40 per cent. therefore is a very safe estimate of the maximum use of this motor on the day circuit, or had the motor been a 1 h. p., which

would have been sufficient to drive the job presses, the use would be 60 to 80 per cent. of the contract hours, probably not above 60 per cent. All printing offices will probably come within this range unless the motor be larger than is necessary to do the work.

Machine shops, doing principally lathe work, as a matter of course use a larger percentage of their contracted power than shops doing lathe and bench work with the same hands. In no case will the service of the motor exceed 65 or 70 per cent. of its contract use; for machine shops, like sewing machine shops, will never average over 75 per cent. of the shop capacity for operators the year round. The average, especially in the case of a shop doing much bench work, will fall as low as 40 per cent.

The driving of laundry machinery, which is our next application, usually proves a profitable contract, according to reports. This fact arises from the intermittent use of the machinery. The heaviest service on the motor will probably be found during the early part of each week, with a general falling off in work during the summer months, while the patrons of the laundry are away at the seashore or in the mountains. In this application, therefore, a 75 per cent. service would probably be an exception, with probably many instances where the service would fall below 50 per cent.

The next application, model and pattern makers, are small users of power, as their occupation requires a large proportion of hand work. Fifty per cent. service in the motor will be found a fair average maximum use, with instances as low as 20 or 25 per cent.

The next application, direct power or belt elevators, is another application frequently met. The average service in the motor is also much smaller than in any other elevator application. Let us suppose a case of the familiar grip connected to the ordinary hand-hoist, with a lifting capacity of 2,000 pounds. In this case the motor is in use only going up, and the usual break is used in coming down. Connected to this elevator, in the loft of the building, we have a 5 h. p. motor wired to a cut-out on the ground floor. We will call the lift 45 feet and the time consumed per trip one minute. We will allow 60 full trips of the elevator, at full load of 2,000 pounds per trip each day. This would approximate 10 car loads of merchandise handled by the elevator, which is certainly above the average. This motor, we will say, is on a ten hour day circuit, its possible horse-power hours, therefore, would be 5 h. p. for ten hours, or 50 h. p. hours per day. Sixty trips of one minute each gives us exactly one hour's service of the full 5 h. p. or 5 h. p. hours. To drive the shafting only while the elevator is coming down or idle, would require about 150 volts or 1½ h. p., and if this was in constant operation the balance of the day, nine hours, its total use on shafting would be 13½ h. p. hours, which, added to the 5 h. p. hours gives us a grand total of 18½ h. p. hours, or 37 per cent. of the contract hours. If, however, the user of the motor avails himself of the cut-out box, and cuts the current out when the motor is not in use, the average use would drop to 20 or 25 per cent. instead of 37 per cent. In the case of a direct power passenger elevator the use might possibly run up to 60 per cent., but this would be exceptional.

Coffee mills will average from 40 to 60 per cent. of their contract hours. Manufacturing jewelers about the same, while retail jewelers will run as low as 25 per cent. Ice cream freezers will not average over 25 per cent., but as the contract season in this case is usually short they should be rated at least on a 50 per cent. basis, except possibly in cases where the customer pays the cost of installation and wiring, which is usual in these cases.

A dentist is one of the smallest of power users, so small in fact, that if every one in a city were connected with a circuit, the load from this cause would never be felt. We will, however, put them down at from 10 to 20 per cent.

The optician uses a motor to turn his grind stones, and its use in this case will average from 20 to 30 per cent.

The last application on the list, church organs, use only from 10 to 20 per cent. of the contract service.

These are, of course, but few of the very many applications of the electric motor; and if, as I trust, the possible subsequent discussion of this general plan may establish a basis for rating motor applications, not only will the objects of this paper be obtained but a question of considerable annoyance now existing between the motor man and the electric light or power company will be solved.

In conclusion, Mr. Chairman, I beg to suggest that the supply and rates of charge for electric power have become of sufficient importance to this association to be represented by a permanent committee, whose duty it should be to obtain from the different members of this association, as far as possible, their experience in the supply of power, in such manner and form as shall be deemed by the committee best suited to the wants of this association.

DISCUSSION.

Mr. Colvin, Baltimore—The paper that has just been read should appeal and does appeal to all electric lighting people who have or contemplate having power service with the irresistible eloquence of dollars and cents. The first thing to consider is whether they will use power; yes. Can they make it pay? Well, it is according to what they will charge for power. If they charge too much every gas engine will get ahead of the electric motor. If they charge too little the power business will not pay. If they adopt a cast iron rule and charge so much a mouth for everything they do an injustice to intermittent power, and if they make a sliding scale, the next city will have a different sliding scale, the customers will get together and the consequence will be dissatisfaction all around; so the paper presented brings up one recommendation of a solution to that problem of classification. I think everyone realizes how important that is. As far as the suggestion of small motors is concerned and their advantage over large ones, the writer says this is but one phase of the much maligned small motor. It is very true. The other phase is that companies starting power usually have an idea that the fan business is the great end of all motor service, and they commence with small power. When they put in larger powers they find the larger motors require less inspection than the small ones. The brushes of the small motors require more frequent adjustment. The small motors in the case of sewing machines have to be opposite the machines and exposed, whereas the large motors can be put in a safe place; and in a city where electrical power has long been in use, you will find, if they have used large power, that they will prefer having a 6, 8 or 10 power motor than a number of small motors.

Take the case where Mr. Lufkin figured out that the company could afford to present the manufacturer with 30 motors. He could, if the 30 motors would run without any trouble. But my experience with both kinds of motors has been that I might get in trouble in that way and have some of these small motors give out—even one or two of them, and I might have the 30 motors back on my hands. In the case of small motors again, there are more sliding contacts of the brush and the commutator, more binding posts shaken loose, more broken adjustments, more money for repairs per horse-power—infinitely more money. As I said before the large motor can be placed, if it is an arc motor with a high tension current, it can be placed away from the operating room entirely where it can only be reached by the inspector. As far as the economy is concerned if the motor is so constructed that the amount of current it consumes shall be a function of the work that it does,—of course you will have shafting against the large motor,—but you will have the satisfaction against the small motor. I do not mean to say that small motors are not successful, but I mean that the average general experience is that there has been more trouble with small motors than large ones, and large motors, as a rule, if they are properly constructed, govern better, require less attention and give better satisfaction. I think everyone appreciates the necessity of having some definite classification of this sort. In visiting a city and talking power with people it is almost impossible to get on any scale. I know of a place in the south I visited recently, where the customer told me he was getting electric power very cheap. I inquired what he was paying; he said he was getting it for $20 a month. It was a ½ h. p. His water power used to cost him more. In other places they will growl at $4 a month.

Mr. H. McL. Harding, New York—There are very many valuable points in the paper which was read, and I hope that the managers and presidents of all the electric light companies will read it over very carefully. It shows a good deal of thought. That is the true way to charge for power—to classify the work. By doing that and carrying it out, even a little farther than it is

done there, each electric station manager will then know just what he should charge, and the moment he feels confident, when he signs his name to a year's contract, that he is going to make money, there will be no trouble in placing motors.

In regard to small motors being more economical than large ones, it may be I do not get the figures exactly right; but taking them as he gave them, with his large motor he was running 14 sewing machines to the horse-power. Now you could easily run with 1 h. p. 20 sewing machines, and even above that. He compares a motor which is only driving 14 sewing machines, with his small motor. Probably he lost very much power in his counter-shafting. That is what I should judge.

Now there is one other point of the business which you all find, I think, of a good deal of interest and value, and it is a new branch that has come up almost since the last meeting—come up on any extended scale; that is central stations supplying power to run electric railways. Now the central stations in each case could do that. You could make up your mind that if a street railway company put up a large central station to run their cars they are going to supply light and power. You may say their charter will not permit that. Probably not; but at the same time the same men may form among themselves a second company. In order to prevent that, it is necessary for you to furnish power to run their railways at a reasonable rate. You must remember that a street car will be operated fully 16 hours a day. In the City of Richmond, they are taking about 5 to 6 h. p. per car. That is an exceptionally difficult road to operate, having grades as high as $10\frac{1}{10}$th per cent., curves 27 feet radius, and other details which make it very difficult. You can therefore take it as a certainty that it will not require on an average for your 16 hours a day over 5 h. p., and from that you can calculate what you should charge. A few data referring to that may be of advantage. In Wilmington they are running now three cars, to be increased to 10. They charge $2.50 per day per car. In Carbondale, where they only pay 10 cents a ton for their fuel, using the screenings, they will run any number of cars, up to six, for $7 a day. In Brockton, Mass., the price is about $1.75 per car, per day. In Richmond, the cost there is a sort of a compound arrangement, because they are supplying light as well as power from the same station, and they estimate that they will charge the railroad company $1.66 per day per car. In a neighborhood where coal costs $3 or $4 a ton and the cars run 16 hours the charge would be somewhere between $1.75 and $2.50 per day.

I present these facts because I think the question will come up before long to most of you in regard to supplying power for the railways in local places. In some of the large cities where the service will be through an underground conduit the electric companies are considering that they will supply 7, 8 or 10 h. p. to operate the road, and they are willing to make such a rate that the railway can afford to take their power from them rather than put up their own station. Of course in that case the margin of profit would not be as large as in the other case.

Mr. Ridlon—I have had but very little experience in the matter of selling power, and have been but comparatively a short time in the motor business. I fail to understand the gentleman's theory thoroughly in regard to small motors being economical. In all other branches of machinery we have always found that where the power was even, a large engine would operate more economically than the small one. I have found it in motors the same. In the first place it takes but one set of wires. You can connect it up with the outside lines as cheaply for a 10 h. p. motor as for a ½ h. p. motor. The inspection for a 10 h. p. motor costs no more than for a ½ h. p. motor. I have found by actual experience that a man who was using a 15 h. p. engine and thought that he wanted 15 h. p. to drive his machinery was not only perfectly satisfied with the power he got from a 10 h. p. motor, but thought he had some to spare and that he could do even with less.

The question that has come up here in regard to the regulation of price for power, that is, charging for what average power is required, seems to me a very important one; that is a question on which hinges a very large portion of the future motor business—getting down to the fact of the amount of power which the customer is using, and the sooner that we can get any actual data in regard to these facts before our association and before our electric light companies, the sooner we can increase the volume of our motor business; and I was in hopes this discussion that we would hear not especially from the motor men, but from the people also who are furnishing the current to the parties using the motors, and I hope this discussion will not close until we have heard from some of the superintendents or managers of the central stations throughout the different parts of the country.

Mr. G. A. Redman, Rochester, N. Y.—We rent 296 motors. We receive $18 for ⅛, $48 for ½ h. p.; $72 for 1 h. p.; $225 for 4 h. p.; $300 for 6 h. p.; $325 for 8 h. p. Of course, you understand, we run all by water and do not use any coal. I would state I have a ⅛ h. p. motor running an elevator, and we find that the average time is not more than twenty per cent.

Mr. Ridlon—I would state in regard to the question of water power, that, of course, that matter would hardly be understood by the steam power people. I am now making arrangements in Maine where the parties will make a very handsome profit, and one that will bring a smile to the faces of most of the members here, should I state it.

The President—It would be a good idea to have those figures. There has not been much smiling this morning.

Mr. Ridlon—They figure their horse-power at $25 a day. I would state the fact that a horse-power costs them $2.50 per year, and they have got 4,000 or 5,000 h. p.

Mr. Lufkin—I would like to say in reply to Mr. Colvin that I think he rather exaggerates the repairing expense of small motors. In the case of one shop, which I referred to, where they had 32 small motors in operation, I took pains the other day to look up the repairs in the shop for the past year, and in that place there have been but two commutators turned out, out of 32 machines, and there has been no armature that has given out. There has been no accident in the shop of any kind from any cause, and the service is reported by the people using the machine as very satisfactory. I do not mean to argue that a ⅛ of a h. p. motor is the only motor that can be used, by any means; but the profits of the electric lighting company arises largely in subdividing their power—in suiting the motor to the work in each case.

Mr. Colvin—I would like to ask if those were run on incandescent lines or arc lines?

Mr. Lufkin—That was on a Brush arc circuit.

Mr. Colvin—Were they run all the time during the year?

Mr. Lufkin—Right through the year.

Mr. Colvin—Did they carry the full $9\frac{6}{10}$ current?

Mr. Lufkin—I understand so. The current in this case is a trifle under $9\frac{6}{10}$; I should say it is about 9 amperes.

Mr. Colvin—The reason I ask that question is that many motors with which I am familiar, owe their length of life to the fact, that although they run $9\frac{6}{10}$ in the night, they run 8 and 8½ all day.

Mr. Colvin—My remarks about small motors were simply from experience of fifteen or twenty cities, where different types of motors were used. I know one or two motors of a very small size that have run better than large ones; yet it seems to me, they were exceptional. What I stated was simply my average experience, and from what these electric light companies told me, and also from their anxiety to get larger size motors and larger generators on the market.

Mr. Lufkin—I think that is rather from a lack of the appreciation of the merits of the case. I think that as soon as the question was thoroughly understood by the electric lighting people, they will take in these small motors, and they will be more ready to adopt a scale, such as I have suggested there, for selling their power.

Mr. Law—We were perhaps the pioneers in the distribution of power by motors. Our first experience was entirely with small motors. Certainly, looking at it from a standpoint of a company furnishing power, and the prices that we are getting for those motors, there is more money in the smaller ones than in the larger ones, beside their not being as hard on the dynamo, as Mr. Lufkin has stated in his paper. We have no very large motors in Philadelphia. In fact, the largest one there is a 5 horse motor running a saw as an exhibition, which is a very poor thing to use as a basis for figuring on. Motors that are upon fan work, in my estimation, are a very poor thing to figure on. It is steady work from morning till night and sometimes from morning to morning. It is a direct drag upon the current. We have but very few motors that are intermittent work. We have two that are on printing presses, and in all cases, I think, the motors that are doing that work have come up to the promises of the company putting them in. We only furnish a current for the motors; we have nothing to do with the motors themselves, excepting to bring the wire to them; we simply furnish the current. Once a month, however, we make a round of all motor places and inspect their condition, and see if there are any changes in the amount of current consumed by the motor. I do not know that I have anything special to say on the subject.

The President—To my mind, motors are the most important development at the present time in electric interests. If you will look around you and see the amount of capital that the various companies have put into this business in the last six months alone, you will find that it is something enormous, and you will find that the companies are not only going into it with the idea of supplying motors of 2, 3, 5, 10, 15 and 20 h. p., but they are going into it with the idea of developing and furnishing power up to 100 horse, and they propose to have, and are making generators to supply that power, to make it a special service; and not only that, but the increase of the factories already in operation is such, as to warrant the belief that they will, within the near future, be supplying generators of even much larger capacity than those named. Now then, if that is the case, if this development is going on, and the money is coming forth, it shows that the people who are putting this money in, have entire confidence, and that the management of these motor companies have entire confidence in the development of the business. This all means that we shall have stations which will employ probably 5,000 or 10,000 h. p. as centres of distribution. We go a step further, and

those centres of distribution furnish not only power for motor service, but they furnish power for railway service, and they not only furnish the power for railway service, but if the electric lighting companies do not take up this question, these very companies, formed originally for power distribution, will take up electric lighting. Now, that is the way it presents itself to my mind, and I had hoped that when this question came before this association this afternoon, the chair would be hardly able to hold down the number of people who would spring up all over the house and want to talk at the same time.

Mr. Ridlon—With yourself, Mr. Chairman, I am very much dissatisfied at not having heard more discussion upon this subject, because I expected electric light companies would come out and make statements in respect to the profits of the power business as compared with the profits of lighting. One thing I know to be a fact—there is quite a gain in that direction; and the power sold to the customer who uses the motor, costs the electric light people far less discount in their bills, gives them far less trouble, and they do not have to exercise that care or inspection that they have to with the lamps. I think one company in Boston have had but one dollar discount on their motor service, where they have had twenty on their lighting service.

Mr. Garratt—I was much interested in the remarks of Mr. Harding, but I was called out of the room, and did not fully hear them. I want to know if I am correct in my understanding, and if we can draw a general statement as to the power required for cars. I understood Mr. Harding to say, that cars are run on an average of sixteen hours a day, and on an average of 5 h. p. That means 80 h. p. hours per day, multiplied by 365—for cars run for 365 days a year—that makes 29,200 h. p. hours a year. I would ask Mr. Harding if it would be a fair statement to say that 30,000 h. p. hours per year, in round numbers, would run a car.

Mr. Harding—I think that would be a perfectly safe figure. The only excess might be that in certain cities they are liable to run one car possibly after twelve at night.

In order that there may be no misunderstanding in regard to what I referred to I would say that I was taking this condition: That the station was already established and had its engineers and firemen, and this was the additional expense for operating the street cars. I did not mean that the company put in this station and pay its engineers and firemen to accomplish this result. This was the additional expense of running cars from the central station.

Mr. Garratt—I understood that. I also understood Mr. Harding to say that an electric light station could afford to furnish a current for those 80 h. p. hours per day for about two dollars per car; that would mean $730 a year for a car. Let us put it in round figures—that wherever a local company wants to put in a 5 horse motor we can say we will let them have this for $800 a year for a car. Would that be a fair statement?

Mr. Harding—Yes, sir.

Mr. Ridlon—I will say for the benefit of Mr. Harding's company, that I was at Richmond with the West End Railroad people at the time they went on to investigate that question of electric railway service, and they were very much surprised at the low cost at which that power was furnished there per car. They could not possibly believe it, although I can see very plainly that it is a matter of fact; and they came to compare it with running horse railways, and they calculated it cost to feed a horse what it would take to run one of those cars a day—$2 a day, where it cost only $1.60 for the power from the electric light station; and that did not allow anything for the cleaning of the horses or the harness or the wear and tear of harness, or interest on amount invested for shoeing, or any other matters; but simply giving him his hay and grain.

Mr. DeLand—Referring to the paper by Mr. Leonard, of Minneapolis, on the use of petroleum as a fuel, Mr. Hart, of New Orleans, has kindly given me some data which may be of service, when we consider that his experience runs over nine months. It appears that the actual savings are over 50 per cent. in the use of oil fuel over coal. The data given me are these: They have been using first quality Pittsburgh nut coal, floated down the Ohio and Mississippi rivers costing $4.50 per ton laid at furnace door. The portion of coal that usually goes to waste costs 25 cents a barrel at Findlay or Lima, and 75 cents at the furnace. As three barrels of oil replace a ton of coal the saving is 50 per cent. There is no burning out of grate bars, no removal of ashes, no smoke in the boiler room. Mr. Hart said that the only disadvantage that they labored under was in respect to transportation. This difficulty they proposed to do away with by the construction of their own tank floats and depots. This company had their own tank costing $14,000. The oil flows from the cars into the receiving tanks, is pumped into reservoirs, passing thence through pipes under the boiler. When the oil is turned on a jet of steam is made to spread the oil flames, so that cold water is converted into steam in 20 minutes or less time.

You will remember that the question of the burning out of the grate bars came up during the discussion of Mr. Leonard's paper. Mr. Hart tells me that he has replaced the grate bars with brick, so that there is a saving effected in that respect.

Regarding the injury that might result to boilers, the fact that the inspector of a boiler company was down there a few weeks ago and approved of their system and congratulated them on their success, would show that there is very little probability of such injury resulting.

Mr. Hart has also kindly sent large photographs of their dynamo room, their furnace room, their engine room, and other parts of their large plant, and they are now in the parlor occupied by the *Western Electrician*.

The President—The chair is exceedingly sorry that he did not know before that the gentleman had that information in his pocket, for he would have called upon him for it. We are much obliged for this information.

Mr. DeLand—I would say, Mr. President, the thanks are due for these data to Mr. Morris J. Hart and Mr. Simon Hart.

Mr. Steuart—I would like to offer a resolution. During the first hour of the session this morning a very important question was disposed of, as I think, with inadequate consideration. The subject of the work of the New England Electric Exchange is one in which I have been very much interested for many reasons. I think it will be of great advantage to electric light companies in giving them competent employés. It also opens a field for honest and meritorious men to find good employment by procuring licenses from such an organization. I believe that during the morning hour the president of the exchange and secretary were, unfortunately, absent from the floor. They are now present, and I would move you that the action be reconsidered, the question opened for discussion, and the president and secretary requested to give us their experience and views on the subject.

Mr. Alexander—I am very thankful to my friend Mr. Steuart, for bringing this matter up again, less because I desire to give any information—I do not know how far you went this morning—but more to be able to state a grievance that I have. I asked the president of the association last night at what hour that paper would be read. The secretary of the association, the inspector of the New England Insurance Exchange were present and myself. We were very much interested in the subject, and naturally desired to be heard. I have stated to the president the nature of the business that called me away this morning and begged him to postpone that subject for a little while. I came here at 20 minutes past 10 and had no idea until 12 o'clock that it had been disposed of, although I was present here in the room at that time. Naturally I cannot say much, not knowing what the report has been; but I understand that there have been some statements made there which the secretary of the exchange, who has labored very hard in the matter, declares were not quite correct. As he knows what these misstatements are I will yield him the floor.

The President—The chair would just state that the statement of Mr. Alexander in regard to requesting a time to be appointed is correct. The chair will also state that every gentleman who has had a paper before this association would like to know the exact minute when it could be presented. The chair would also say that he does not know where gentlemen are to be found at any particular time, and that it is the duty of every member of the association to sit in this body from the time of the opening of the first session to the last moment of the last session. That is the only apology the chair has to make for any little inadvertence on his part. If he has failed to accommodate everybody it is simply because he could not look all over the City of New York and put the right man here at the right moment.

We shall be very glad to hear from the secretary of the New England Exchange.

Mr. H. B. Cram—The turn that this matter has taken, Mr. Chairman, has been somewhat of a surprise to me, and only within an hour did I know that the paper had been read. I had an opportunity of merely glancing at the paper—nothing further—and as in a very few moments I shall have to leave, I shall endeavor to make my remarks as brief as possible, and at the same time to convey some information which will be of interest to every member of the association. In New England we are pleased, I think I may say, with the Insurance Exchange, which has gone to work at the right end of the problem as to the relations existing between the insurance interests and the electrical interests. The electric light committee of the New England Insurance Exchange has for its chairman a gentleman who has devoted a great deal of his time to the subject, and from the start that exchange has evinced a very decided interest and determination to bring the insurance interests and the electric light interests into absolute harmony, in order that they may recommend what they believe the facts warrant them in doing, the installation of means of distributing energy by electricity, in preference to any way or purposes of illumination or of transmission of power. They have already taken several steps in that direction. They have offered a reduction in rates in certain cases where electric light is used as an illuminant in preference to gas or other means. When the matter of inspection was started, there was naturally more or less inertia, and it was finally discovered from experience that while the Insurance Exchange could inspect apparatus and installation it could not inspect men. As a result of that discovery the New England Electric Exchange was formed; to put it very briefly, in order to provide

some means for inspecting men. The exchange was formed as a result of a meeting, to which the insurance men were invited and the electric light men. The Boston Electric Club very kindly tendered the use of its rooms for the first meeting. After the formation of the exchange the New England Insurance Exchange, in order to give the matter authority said, "on and after October 1st the New England Insurance Exchange will require that all persons engaged in installing or operating electric plants, shall hold a license from the New England Electric Exchange." The Boston fire underwriters immediately indorsed that action. In a general way the plan was simply this: A plan of licenses was adopted, as I have already stated. Examiners were to be selected from men possessing theoretical and practical knowledge. The applicants were to be examined and passed upon by those examiners in order that the insurance people should be fully represented, and there might in no event be any question of the action of the exchange. It was decided that the inspector of the insurance exchange should countersign the insurance certificate before it was issued and became a certificate. I mention that fact thus particularly because I have observed that there has been an erroneous opinion existing. It has been thought by some that the New England Electric Exchange was simply the New England Insurance Exchange, and that they proposed to coerce electric light companies and electric power companies. There could be no greater mistake. The object is that the two exchanges should work in harmony, and our experience thus far has shown that while there may possibly be some crudities, nevertheless the plan is a good one and is practicable, and we are fully justified in saying there can be no possible question as to its ultimate success. Wherever a misunderstanding has existed it has been a matter of a very few moments' conversation to correct the misunderstanding.

After all that has been said during this convention about the absolute necessity of satisfying the subject that electrical energy can be safely distributed, it goes without saying, it seems to me, that there is an absolute need for some such body as the New England Electric Exchange. I believe that such exchanges should exist throughout the country. I further believe that they can only work in harmony with the insurance interests. I believe there is no other way in which their work can be made obligatory or binding. I believe in that way it can be made so, and without in any way interfering with the legitimate work of an electric company, whether light or power, or with the work or duties of any employé, from the highest to the lowest. We have found an increased interest among the employés. They feel that possessing a license, obtained after passing an examination, that their work will be better respected, that they will have the confidence of their employers, and also the confidence of the public. Our experience teaches us, I would say, in conclusion, that we are justified in predicting that, after the Electric Exchange has had time to fully demonstrate the purposes for which it is organized, there will be less heard throughout the public press of the danger to life and property arising from the electrical distribution of energy. [Applause.]

Mr. Steuart—Mr. President, I see that the time for the discussion of this subject has passed. Therefore I shall not attempt to add anything to what has already been said, but only to offer a motion that the committee that made a report to-day be increased to five members, and be continued, with instructions to bring in a report at the next meeting of this convention upon the desirability of establishing a national exchange in connection with this association; and I would respectfully suggest to the chair that the president and secretary of the New England Exchange be made members of that committee.

Mr. DeCamp—There seems to be a little difference here in respect to this report, and I find I am a member of that committee, and I plead guilty to a dereliction of duty. But I think the disposition made of the report offered by Mr. Ridlon, under the circumstances, is the best possible. As I understand, that report has been received and filed and the committee continued.

Mr. Steuart's motion was carried.

On motion of Dr. Moses the convention then adjourned till 3 o'clock, reconvening in the parlors of the Electric Club at that time, President Duncan presiding.

Mrs. Morrison, Mrs. Duncan and Mrs. Garratt were present.

AFTERNOON SESSION AT THE ELECTRIC CLUB.

PRESENTATION OF TESTIMONIALS TO MR. J. FRANK MORRISON AND MR. GEO. WESTINGHOUSE, JR.

Dr. Moses—It has been my pleasant duty, ladies and gentlemen, to be the depository of a secret for the last three months. You all know there is a certain pleasure about letting secrets out. It has been the desire of numerous friends of our honored first president of this association to exhibit to him in some way the esteem that they have for him, by giving him something that he might recollect, since he has frequently given them to recollect, while he was presiding over them, that would keep them always in mind. This time they have managed, I think, to embody something that will suggest to him something new every time that he looks at it; because a man's mind, after all, is suggestive and a man can find a world in a drop of water if he has imagination enough to see it.

There is crystallized in this box all the good feeling, appreciation and good fellowship that has actuated every member of the association towards Frank Morrison. We have tried to embody in this his life—and there is symbolically typified upon it something representative of the different phases of his active existence. In the first place we have started out the idea that it should be simple and strong: we have tried to paint this thing in black and white, and we hope that he will read between the lines in it all the good feelings that we have for him.

At the risk of being a little prolix I will explain the designs here, which represent, ladies and gentlemen, a good deal of hard work on the part of the principal men at Tiffany & Co.'s, who entered into it *con amore* I assure you. We see on a very simple base a silver box, having inscribed upon it this: "Presented to J. Frank Morrison by his friends of the National Electric Light Association, New York, August 31st, 1888." On this base we have three barriettes, one representing a continuous current machine, the centre one an alternating current machine, and the third a machine for the distribution of electric force. The first one is a Brush machine, and I think in the hands of Frank Morrison it did as much as anything else to establish the fact that electricity could be distributed from central stations profitably. In the centre we have a machine that was brought to the notice of the association at a time when he presided over it, and in the most advantageous way, as I recollect, to me, because he descended from the chair, took the part of the association, and defended them against innovation.

Third and last, but not least, there is a Baxter motor. Mr. Morrison represents the Baxter motor as head, front, president and everything else. It is a means of distributing force into something that he—so typical of him—has at heart, that by a very happy thought on the part of Mr. Whitehouse it has been embodied in a design so appropriate that he thinks of employing it for other purposes. All around you will find the Baxter motor worked up like a Greek honeysuckle. It makes a very beautiful decoration; so that the base of this thing is a Baxter motor. On the faces of this you will see Baltimore, whence Mr. Morrison comes; New York, where he receives this token; and on these sides are represented the places where all our conventions have been held—Baltimore, New York, Chicago, Detroit, Boston, Philadelphia, Pittsburgh.

By the bye, I must turn off the switch here in order to get at the key, that was introduced to typify in some way Mr. Morrison's connection with telegraphy, and through all the various progress by which he has reached the position of being the first president of the National Electric Light Association, which means not only the electric light but that upon which the electric light shines.

Here, sir (taking from the box a silver-mounted gavel and presenting it to Mr. Morrison), is an insignia of office that you have wielded so successfully at the head of all our conventions. The National Electric Light Association, I think, more than to any one else, owes its existence and successful development to you. It was by means of that little instrument, a symbol of power seldom used, except for good, that we would typify you with. We have been ruled by it, and we have frequently kissed the hand that bore the rod. Upon this is an inscription: "J. Frank Morrison—1885–1888; First President National Electric Light Association." Here is something typical of an electric cable, in order that you may with this in your hand hear yourself in contact with every one whom this is intended to govern. This is an insulator. The president must be insulated from all the influences that prevail on the floor of the assembly. [Applause.] And we thought that to have been the best symbol that we could put upon the gavel.

Here, sir, you have a cable surrounding this, which represents, strand by strand, that by some attachment of the heart every member of the association is in close contact with you, and always on the call.

Here is your monogram surrounded by a laurel wreath, which you deserve; each leaf represents, by the skill of the silver beater, an incandescent lamp, and the whole of it blossoms, at the top, into light. On this side you have an arc light—a Brush arc light, which you first tried, I think, in Baltimore, before the public, in a successful way; so that I think that we have, in this respect, typified all your connections with electric light interests, and here is the key of it, which is also the key to our hearts. You will find that it is made of wire, and it is a short circuit to us. [Applause.]

Mr. Morrison—Mr. President, Ladies and Gentlemen:—"They say that the most trying time to the soldier is when he is under fire and cannot shoot back. I take it for granted that those of you who have been brought suddenly into a position of this kind, can have some little sympathy with the soldier. The fire of compliments that I have received for the last fifteen minutes is enough to break the nerve of a man of much more self-possession than myself. In discharging the duties devolving upon the president of the Electric Light Association, I have not always been able to do that which would, as Dr. Moses suggests, make them wish to kiss the hand that wielded the rod. I think they felt more like having that rod themselves a little while sometimes.

But a man can discharge a disagreeable duty honestly, and will at the end of it get from all fair minded men that reward which is always better than anything else—fair treatment in return.

"My connection with the National Electric Light Association has been a very pleasant one. It has been a sort of channel through which I have made friends in every part of the country. It makes no difference whether I am in Maine or Texas, I find members of the National Electric Light Association, an organization which was born only four or five years ago. I find friends spread all over the country, and in every case extending a hearty greeting and a hand of friendship. In that way I feel amply repaid for all the troubles that fall to the lot of a presiding officer. It has made the labor of the president of the National Electric Light Association a labor of love, and the appreciation which the gentlemen of this association have shown for my poor endeavors are ample payment. It was not necessary to present me with so valuable a gift to make me carry the memory of every one of you in the most kindly manner in my heart. The National Electric Light Association is still something like a young bear—a good deal of its troubles are ahead of it, and if you have not committed an error to-day in some of your legislation, I think that a new generation will fill the vacant places, which men of our time of life must soon make in the ranks of the membership of the National Electric Light Association, and these men taking up the work as we leave it off, will turn back to the records of the association and will find, although it was born in storm, it was at this time pursuing its vision calmly and harmoniously. This association was born in storm and under the most peculiar circumstances of suspicion and jealousy. That sounds strange, doesn't it, to you men who are so friendly to each other to-day. The organization of the National Electric Light Association was made by men who, not expecting to gain any benefit, were afraid to ignore a call which was made for electric light men to meet in Chicago, for fear some other fellow would get a benefit they did not possess. Yet that most sordid motive has led to the most favorable results.

"Only a few hours have slipped through the hand of time, since I was made the recipient of a gift and testimonial, handed to me on the floor of the association under circumstances, which make it most embarrassing for a man to say what he ought to say; and here I find myself brought face to face with a most expensive gift—the gift of gentlemen to whom I have not always been exactly kind, I believe, though,—I hope—I have been just. You can understand, therefore, that in rummaging through the junk-shop of my head for something suitable to say, it is not easy to find the kind of metal you need, so whatever breaks there are in my talk, you can just charge to that, and ask yourselves if you would be able to do anything better if you were in my place. My position, I confess, is a most embarrassing one, one in which, in the future, if I am on a committee, and I have the honor of presenting to the retiring president of the association a testimonial, I pledge my word of honor I will never place him. I thank you for your courtesy; I thank you for the kindness you have shown me through our course of electrical tribulations.

"I thank you for all the kindness you have shown me during all these years. It is not necessary for me to tell you that I will remember it as long as I live, for I could not possibly forget it if I tried, and I would not if I could.

"Before I step back, I want again to call your attention to a remark I made a moment ago. Within the next twenty-four months will be determined the question whether the National Electric Light Association will become a permanent institution, or whether it will pass away, as thousands of other associations have passed away, leaving hardly a trace. This, to-day, is the strongest electrical organization ever gotten up in this country. It is not strong in members, but it is strong in its firmness of purposes and it is strong in the intentions of its members up to the present time. They, I am happy to say, have been able to eliminate every feeling of personal advantage, and have met upon a common footing; now, with that feeling, I say, guard yourselves against suspicion, against jealousy, and whenever a question comes up which you will be called upon to decide, think first, not what will this do for me; you, gentlemen of New York, do not stop to think what it will do for the New York Electric Club. You, who are engaged in the wire business, do not say what will this do to the advantage of my business; but knowing and feeling that neither social organization nor private business can be advanced or live unless you act on the basis of fairness and honesty, when these questions come up, give and take until you get a synchronism along the whole line.

"This is the first chance I have had in my life of talking before ladies. I have only fear of one. (Laughter.) One of the difficulties of a man untrained in speaking is the difficulty, not of what to say, but where to stop. I never have been able to find that point, and so have to break off just as abruptly as I do now. Gentlemen, I thank you." (Applause.)

Dr. Moses—There is one other very pleasant duty that has been thrust upon me like greatness upon many men, and if Mr. Byllesby is here, the representative of one of the Westinghouse interests, which contributed so pleasantly last winter to entertain us while in Pittsburgh, I would be glad to say to him what I have to say. (Mr. Byllesby was not present.) Well, as our honored president lives in the same town as Mr. Westinghouse, I would be glad to address him, or if the president of the club will accept the gift for Mr. Westinghouse, it will serve our purpose.

This, gentlemen, is a little testimonial from the association. I will not say a receipt in full, but a receipt on account of the National Electric Light Association for many kindnesses extended by the interests represented by Mr. George Westinghouse, Jr. The inscription, however, I think, will convey in a very few words, just exactly what was intended to be conveyed: "George Westinghouse, Jr., from the National Electric Light Association, in grateful recognition of numerous attentions and substantial favors extended by his various companies during the Pittsburgh Convention, February 21st, 22d and 23d, 1888. Presented New York, August 31st, 1888." I would like to recall to your mind that Mr. Westinghouse's company, in a very delicate way, sent us quite a number of checks which amounted in the aggregate to some $1100 or $1200, which were accompanied by the express wish that the subscription might contribute in some way to the publication of the valuable proceedings of this association. The best return we can make for the field given to us is to present the donor with the fruits which it produces, and we have here a copy of our transactions bound, in, I hope, an appropriate way to convey at least, our delicate sentiments to him. They are contained in a case, that he may keep by him in such way as to remind him from time to time of his relations to this association, and how they were pleased to enjoy his hospitalities. Gentlemen, if Mr. Byllesby is not here, we will then send the box to Mr. Westinghouse, with the compliments of the association.

The convention then adjourned.

The following is a list of gentlemen present during the convention:—

Auburn, N. Y.

Simpson, F. C.

Baltimore.

Colvin, F. R.
Evans, D. E.
Harding, W. H.

EXHIBITS.

During the convention exhibits were made, in various parlors and rooms of the Hotel Brunswick, by companies and firms as follows :—

American Electrical Works, Providence—Insulated wires and cables.

The American Waltham Watch Co.—Non-magnetic watches.

The Baxter Electric Manufacturing and Motor Co., Baltimore—Photographs illustrating the use of the Baxter motor in many places where they are now employed.

The Bernstein Electric Manufacturing Co., Boston—Series incandescent lamps.

The Callender Insulating and Waterproofing Co., New York—Solid underground system and "Trinidad" line wire.

The Campbell Electrical Supply Co., Boston—"Vulcan" wires and cables.

The Eddy Electrical Manufacturing Co., Windsor, Conn.—Electric motors and speed indicators.

The Electrical Accumulator Co., New York, and **The Electro-Dynamic Co.,** Philadelphia—Storage batteries and appliances.

Electron Manufacturing Co., New York—Dry batteries.

The Eastern Cable Co., Boston—"Clark" wires and cables.

The E. P. Gleason Manufacturing Co., New York—Electric light shades, globes, etc.

The E. S. Greeley & Co., New York—General electrical supplies.

C. K. Giles, Chicago—Anti-magnetic shields for watches, and experimental apparatus illustrating their operation.

The Grove Electric Co., Philadelphia—Meters for lamp-hours.

Hill Clutch Works, Cleveland, O.—Couplings and pulleys.

Hurlbut Flexible Conduit Co., New York—Flexible conduit for underground wires.

C. L. Ireson, Boston—Leather link belting.

A. B. Laurence, Representing the Underwood Manufacturing Co., Tolland, Conn.—"Cotton-leather" belting.

Law Telephone Co., New York—Batteries for telephones.

Locke Brothers, Salem, Mass.—Damper regulator.

C. McIntire & Co., Newark, N. J.—Joints and connectors for electric wires.

National Conduit Manufacturing Co., New York—Conduit system.

The New York Insulated Wire Co.—"Grimshaw" wires and cables.

Non-Magnetic Watch Co., New York—Paillard non-magnetic watches.

The Okonite Co., New York—Insulated wires and cables.

The Phœnix Glass Co., New York—Electrical glassware.

E. E. Pettingill & Co., Boston—Electric light, telephone and telegraph supplies.

James W. Queen & Co., Philadelphia—Electrical testing instruments for both laboratory and practical use.

The Standard Carbon Co., Cleveland, O.—Electric light carbons.

The Standard Underground Cable Co., Pittsburgh—Insulated wires and cables.

Standard Paint Co., New York—Waterproof and preservative paints and compounds.

Sprague Electric Co., New York—Their latest form of motor.

The Schenck Belt-holder and Shifter Co., New York—Model of belt-holder.

The Sawyer-Man Electric Co., New York—Incandescent lamps, fixtures and appliances.

The Simplex Electrical Co., Boston—"Simplex" wire and insulators.

The Stilwell & Bierce Manufacturing Co., Dayton, O.—Photographs of their "Victor" turbine.

A. Schoverling, New York—Dry battery.

Chas. A. Schieren & Co., New York—Electric leather belting.

The Thomson Electric Welding Co.—Specimens of electric welding.

Union Indurated Fibre Co., New York—Battery jars, conduits, etc.

Western Electric Co., Chicago and New York—Long-distance telephone desk, with telephonic connection with the city exchanges for use of members.

T. Wallace, Ansonia, Conn.—Conduit for electric light wires.

THE

ELECTRICAL ENGINEER.

Conducted by F. L. POPE AND G. M. PHELPS.

PUBLISHED MONTHLY AT

11 Wall Street, New York City.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *11 Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. VII. NEW YORK, OCTOBER, 1888. No. 82.

SUBWAYS AND COMMISSIONERS.

NO topic occupied so much time and attention at the recent electric light convention as the underground wire question. The pointed and pithy address of Mayor Hewitt, on the opening of the convention, was a sort of "key note" as the politicians say, and would have served to concentrate the minds of the assembled electric light men upon subways and subway commissioners even if the members of the association had not come to New York with their heads full of the subject.

New York having enjoyed the advantage of having a subway commission for some four years, was, not unnaturally, expected to offer the gathering of the electric lighting fraternity some reasonably satisfactory solution of the underground wire problem. What then was the general surprise when His Honor the Mayor called upon the association to put their wits at work on the subject and to tell New York and its Subway Commission what to do with arc light wires?

Notwithstanding the value and interest of the papers and discussions that followed, on various aspects of the question, it is needless to say that the Electric Light Association offered no solution of the problem in response to the Mayor's request. They contented themselves by a resolution of "hearty sympathy with the views expressed by His Honor, Mayor Hewitt," and including an expression of the "opinion that up to the present time no commercially practical method has ever been brought to their notice by which high tension direct currents, such as are used for arc lighting, can be placed underground." We take the liberty of saying that a resolution recommending the immediate discontinuance and abolishment of the Subway Commission would have been much more to the point, and not less in accord with the Mayor's convictions as expressed and implied in his address. In fact, we believe that much competent opinion would be found to favor the suppression of that ridiculous body, as a wise preliminary step towards a satisfactory solution of the electric wire question. However desirable such measure might be, it is not likely to be accomplished, for, as Mr. Hewitt remarked, the commission was made up of men supposed to understand politics though they knew nothing of electricity. They have known enough to promote the organization of a company to construct, own and control the conduits and to rent them to the electric companies. This is undoubtedly the most objectionable feature of the situation from the point of view of the electric companies, or at least such of them as are not shareholders in the conduit company; and their objection is well founded.

The commission has distinctly failed to accomplish the purpose for which it was created, to wit: the adoption of a general system of subways for all the electric wires of the city. In view of the imperfect state of knowledge and practice on this difficult problem, the failure of a board of politicians to solve it is not at all surprising.

In several other cities, notably in Chicago, electric lighting companies are putting down their own conduits, and gradually, by the aid of knowledge and experience, reaching sound and trustworthy methods. They do not suffer from the lack of a Subway Commission. We believe electric light men now generally recognize the ultimate necessity, and even ultimate economy, of underground conductors; and that in their hands the difficulties of the work to be done are far more likely to find solution, than in the hands of such a body as the New York Subway Commission.

There can be no doubt of the necessity of the regulation and control of electric wires on the part of the municipal authorities. The tardy recognition of this need is already bearing fruit in the work of removing dead poles and wires and establishing something like order among overhead wires, recently begun by the commission under the lead of its expert, Dr. Wheeler. They may well suspend underground work and find more useful employment for some time to come in regulating existing pole lines.

Although this work could be done just as well under the direction of an expert, by the Department of Public Works, yet, inasmuch as we have the commission, and it seems to have come to stay, let it be made useful.

PROFESSOR RICHARD A. PROCTOR's death creates a noticeable void in the ranks of scientific workers and writers. Through his long continued and successful work in bringing scientific knowledge and methods of inquiry before general readers and the public, in his writings and lectures, he became very widely known and appreciated outside of scientific circles. He did not disdain ordinary topics, and discussed the game of whist with scarcely less interest and vigor than he displayed in his astronomical writings. He showed little of the impersonal

tone characteristic of the highest type of scientific mind. His more personal or intimate style was exceedingly well adapted to make scientific discussion attractive to the general public. The usefulness of his work is undoubted. It is gratifying to recall the success and high estimation which he achieved in the United States.

It is rather too bad that nearly all, if not all the journals which reported the recent convention of the National Electric Light Association, except the Electrical Engineer, should have spoiled the point of the felicitous quotation of Dr. Arnold used by Dr. Moses in his report as chairman of the executive committee—viz., "A teacher is a man who is striving all the time to make himself useless." Either stenographers, reporters or editors thought this could be bettered by writing "useful" instead of "useless," and gratuitously made the alteration. In the discussion on fuel, following Mr. Leonard's paper, on "Petroleum Fuel," Mr. E. R. Weeks, of Kansas City, having stated that his coal cost $2.56 per ton, was asked what kind of coal he used, and his reply is variously reported as "not bituminous" "non bituminous" and "bituminous" instead of "bituminous nut," as it stands correctly in the Electrical Engineer Extra, of September 15. These errors are not of great importance, but they illustrate the difficulty of reporting proceedings accurately in a race for priority of publication.

Why would it not be a good plan for the New York Legislature to complete and round off its capital punishment by electricity act, at its next session, by creating the office of Lord High Executioner for the state, and including an enactment that Harold P. Brown, Electrical Engineer, shall be appointed to the office for life or during good behavior?

The 28th meeting of the American Institute of Electrical Engineers, and the first of the present season, will be held at the house of the American Society of Civil Engineers, 127 East 23d street, on Tuesday, October 9, at 8 o'clock, P. M.

The programme of the evening will be the discussion of Mr. Frank J. Sprague's paper, on "The Solution of the Municipal Rapid Transit Problem," which was read at the last special meeting of the Institute, June 19, last. Messrs. M. B. Leonard, of Richmond, George W. Mansfield, of Boston, and Robert W. Blackwell, of New York, have signified their intention of taking part in the discussion, and other members who have made a study of the subject are expected to be present and participate.

The meetings of the Institute are open to all who desire to attend, and it is hoped that many persons who are not members will be present at the next meeting. The officers and managers of street railways will find much to interest them in the discussion.

At the recent meeting of the British Association for the Advancement of Science, no less than 37 papers on electrical subjects were read. The authors comprised men distinguished in electrical research, invention and practice, their topics covering a wide range of both theory and application. With all this wealth of scientific and technical knowledge Great Britain has, says Professor Ayrton, hardly 100 electric motors in use while America has already 6,000. We must still admit that our English brothers keep ahead of us in research and theoretical discussion, but we somehow get electrical contrivances made, tried and in commercial operation before we know much about their theoretical properties.

Our slap-dash manner of plunging into business with new electrical devices has, of course, its disadvantages, and would be disastrous, perhaps, but for the freedom of movement and recuperative resources attendant upon our industrial conditions. We learn from experience, more than from theoretical considerations, to revise our methods and to reconstruct our machinery; experience which, however costly, is seldom ruinous. From the establishment of the telegraph down to the commercial introduction of electric lighting and motive power, the course has been the same, viz.: doing the work at first "by main force and violence," to use the language of an old telegrapher. In the case of the telegraph it took us over 20 years to find out how much trouble and money could be saved by adequate attention to a few elementary electrical principles, —but meantime we had established the most widespread and general use of telegraphic communication in the world. In the more recent industrial applications of electricity, particularly in electric lighting, the displacement of crude methods and the adoption of sound principles of construction and operation have come much more speedily than in the case of the telegraph, though much yet remains to be done, particularly in the matter of line construction.

When rough or inadequate methods or construction jeopardize human life, the rapid development of a new industry is purchased too dearly. Two runaways of an electric street car within a fortnight, down the same steep hill on a city railway route, are at least one too many. The plunge of a motor and car down Mount Oliver, at Pittsburgh, August 13, severly injuring the conductor and a lady passenger, was a sufficient warning; but on the 28th of the same month a motor and car escaped control and ran down the same hill, both motor and car being wrecked and seven persons injured badly, one, as reported, fatally. Failure of mechanical appliances for controlling the descent is alleged as the cause of the disasters.

In the number for January last, the Electrical Engineer, commenting on electric car machinery, said :—

> A well-known electrician of our acquaintance had occasion a short time since to consult a manufacturer of locomotives, whose street railway motors have attained a national reputation for economy and general efficiency, with reference to the construction of an electric motor. The manufacturer at once exclaimed that it was useless for him to estimate on electric machinery, as he had found by experience that electrical people would not pay for the quality of workmanship that was required for proper locomotive running gear. What they wanted, he said, was a cheaper class of work, such, for example, as that used in a rather poor grade of agricultural implements.
>
> * * * * we have noted a certain disposition on the part of some electric railway people to undertake what may be called feats of sensational engineering, such as running over imperfect tracks, and up and down impracticable gradients, and the like. There is no reason whatever to suppose that an electrically driven locomotive can run with safety where a steam driven one cannot, yet it is quite apparent that many people who ought to know better are being carried away with the delusion that any railway

problem that presents peculiar difficulty can be solved at once by the application of electricity.

THE establishment of an office and headquarters of the National Electric Light Association in New York, under the permanent charge of an electrical engineer as secretary and treasurer, determined upon at the August meeting will soon be an accomplished fact, and cannot fail of usefulness to the association. It is understood that Dr. Allan V. Garratt, of Boston, will accept the charge of the office, and will soon remove to New York to assume the duties of secretary and treasurer. Dr. Garratt will be cordially welcomed to this city.

OBSERVATIONS.

NEWSPAPER science still flourishes in Canada as well as in the United States. There recently fell into the observer's hands a copy of the Montreal *Herald*, in which was a special from London, Ontario, to the following effect:—

"Sept. 17th.—Harry Walker, an employé in the Ball electric light station, had a narrow escape on Saturday night. He happened accidentally to form the connecting link for the electric current, and was knocked insensible. *When two policemen picked him up his body was so full of the fluid that they both received bad shocks.* He was finally taken out of the station and placed on the ground, and soon came round."

One notes the completeness of this account, its *multum-in-parvo*-ness so to speak. We are driven to one of two alternatives. Either we must go back to the fluid theory of electricity, or we must assume that the fluid with which Mr. Walker was filled, and which shocked two policemen, was not electric fluid but some other fluid.

Further, that the operation of laying Mr. Walker upon the ground appeared to subserve the desired purpose of discharging him.

. . .

THE above utilization of the earth as a discharging train, calls to mind the recent reading of some Western historical notes, in which the discovery of the earth return was attributed to Messrs. Reid, Reilly, and O'Connor. As might have been expected Mr. Reid comes to the front with a disclaimer, which is embodied in some most interesting historical notes.

The electrical use of the earth is, in fact, much older than telegraphy, and formed an element, albeit an unrecognized one of Stephen Gray's experiments on conduction.

As early as 1746 Winkler discharged Leyden jars, using the river Pleisse as a discharging rod. Le Monnier, Watson, Franklin, and De Luc successively made similar and more exhaustive experiments, and fully verified these results. These were, however, all experiments with high potential electricity frictionally developed.

Basse, of Hameln, in 1803, used water and damp ground to form part of a battery circuit.

Basse was followed in the same year by Erman, of Potsdam; Aldini, of France; and eight years later Soemmering and Schilling.

Steinheil used the earth as a return wire for a telegraph line in 1837, and was the first so to do; but the most remarkable prior suggestion was that of Faraday, contained in his note 292, series iii.; which states, "A good discharging train was arranged by connecting metallically a sufficiently thick wire with the metallic gas pipes of the house, with the metallic gas pipes belonging to the public gas works of London; and also with the metallic water pipes of London. It was so effectual in its office as to carry off instantaneously electricity of the feeblest tension, even that of a single voltaic trough, and was essential to many of the experiments.'

It appears that Faraday used as early as January, 1833, the date of the above note, gas and water pipes as grounds just as we do now.

There are lots of things in Faraday's experimental researches, that have since been invented.

. . .

IT is gratifying to note by the paper of Mr. E. R. Weeks (read at the recent electric light convention) that the necessity of thorough electrical education is recognized at Kansas City. The Gramme Society of that place moves ahead in the right direction. The spread of such societies will probably tend to increase the class of men who have found out that with increased knowledge they don't know as much as they thought they did, when they thought they knew it all. But when they reach that stage they will be better workers and better citizens.

. . .

THE observer sees that a new electrical paper has appeared in Kansas City, entitled the *Electro-Mechanic.* Volume I., No. 2, gives the interesting paper of Mr. Weeks in full.

It may be conjectured that some one connected with the *Electro-Mechanic* has, in the dead past, been one of that misguided class who have infringed the patents of the Bell Telephone Company, and who have, in consequence, felt the heavy legal hand of that company, for we find that in the list of books owned by the Gramme Society, according to the *Electro-Mechanic*, is Prescott's "*Hell's* Speaking Telephone."

. . .

THE West End Railway Co., of Boston, wants to apply electricity as a motive power wherever it can; and it wants, in some aristocratic districts of the Back Bay, to use the overhead wire system. Although the said company tries its best to make the adjacent residents believe that an overhead wire and its supports for an electric railway are things of beauty and joys forever, some of them stubbornly refused to be persuaded, and at a recent meeting of residents in remonstrance, Frank Morrison, for himself and others, appeared, and among other startling statements delivered himself of the following. "The centre wire must be insulated its entire length, a new thing on our streets, *so that if touched by a man it will pretty near kill him.*"

What an age we live in to be sure.

. . .

HERE is an observation thrown in *de bene esse.* A Tennessee negro (says a Nashville newspaper) has just been put in prison for being too smart. He couldn't see why he as well as others should not practice on the negative side of electricity. His crime was selling glass marbles to his "cullud brudders," as a protection against lightning. He stated in making his sales that they were made from glass telegraph insulators from which they derived their efficacy, and his price for each marble was 40 cents. Perhaps this nice little business *was* a little crooked, but the enterprising darkey does not understand why he should be singled out for incarceration and other quacks go free—nor indeed does the observer.

. . .

A PROPHET is necessarily an observer; if he is not, his prophecies will not in the end be profitable.

But the observer is not a prophet. He does not daily predict the wonderful things which are to be hereafter accomplished by electricity.

Nevertheless he desires to state that the patents for electric railways and locomotion issued from the United States Patent Office during the month of June 1888 alone, are approximately equal in number to one-third of the entire list of similar patents issued during the year of grace 1886.

. . .

JOURNALISTIC enterprise—in the business department—can be said to have reached the dignity of a high art in the following instance. The observer notes that the New York representative of one of our bright periodicals has secured the services of two assistants; one of whom is a tenor soloist of acknowledged ability, and the other an assistant editor of an orthodox religious publication.

ARTICLES.

THE COPPER VOLTAMETER.

BY LIEUT. G. L. ANDERSON.

When ordinary care is taken, copper electrolysis affords the means of standardizing current measuring instruments with great accuracy. The limit of error need not exceed $\frac{1}{50}$ of one per cent. which is far within practical requirements. Results in still closer agreement can, no doubt, be obtained by the silver process, but the copper voltameter requires less skill and labor in manipulation, costs less to purchase and use, and it is sufficiently accurate through a greater range of current strength, current density, density of solution and temperature.

It consists briefly of two series of parallel copper plates suspended vertically in copper sulphate solution. If a uniform current be sent through the solution from the plates of one series to those of the other, the weight in grammes of copper deposited on the latter in one second divided by .0003287 will, if the requirements are fulfilled, be the strength of the current in amperes and the value of the deflection of a galvanometer in the circuit. The divisor will differ slightly from .0003287 if the temperature or current density vary much from the normal.

For currents less than five amperes, the ordinary cylindrical battery jar may contain the solution and support on its rim rectangular cross-pieces, each having a brass spring or wire clip bearing at the middle for holding a plate. Or the plates may suspend from the cover. Three plates—two, anode and one, cathode—are each cut from rolled sheet of pure hard copper into a circular or rectangular form, having a tongue piece (3 × 2 cms.) The edges and the corners, if any, are rounded off and smoothed. Usually the cathode is two or three centimetres longer and wider than either anode, and should be as thin as possible, and yet sufficiently stiff so as not to be bent in cleaning. The tongue piece projects from the middle of a side of the plate, and in position is held by the spring on the cross-piece. It is the only part of the plate above the surface of the liquid. The cathode is suspended between the anodes parallel at about a centimetre distance, and insulated from them.

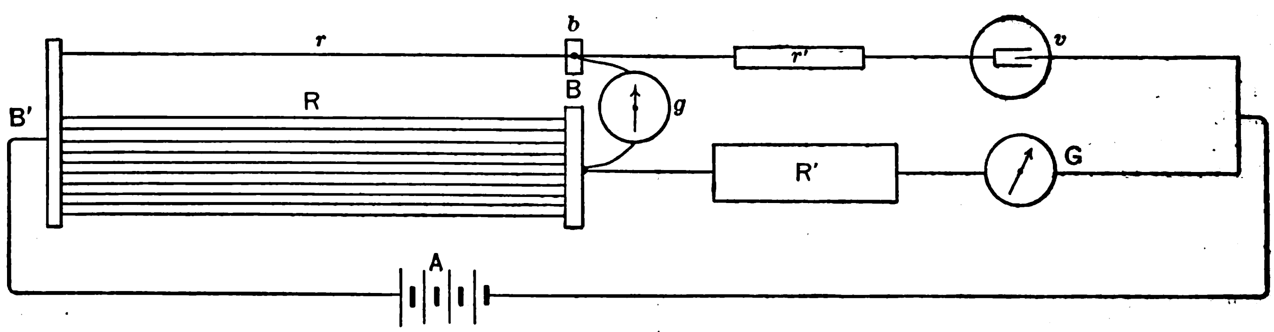
For large currents the size or the number of the plates may be increased. If the latter, there will be one more plate in the anode than in the cathode; the plates of one will alternate with those of the other, and will be insulated from them as above. The Germans use platinum for the cathode, and the results obtained with it agree with those from copper to within $\frac{1}{5000}$.

The cleaning of the plates prior to immersion, and the washing subsequent to it, are important operations requiring only a short time if properly done. The cleaning consists in polishing the surface with fine clean, dry sand paper, which is wrapped about a wooden cylinder and revolved in the lathe. The plate is held tightly against the cylinder by means of a pad to avoid touching the surface of the plate with the fingers. The dust is then wiped off with a soft brush or silk pad, or washed off in clean water. If slight oxide remains, as shown by the coloring, the plate is put in slightly acidulated water. If thickly oxidized, as with new copper, it is wetted and placed a few seconds in strong nitric acid, then washed under the spigot and, in order to prevent oxidation, put in a tray to which a few drops of acid have been added. The anode is first suspended in the bath. The cathode is rinsed off and dried, first between two sheets of filter paper and, afterwards, by a current or before a fire or lamp (not over them). When cooled to the temperature of the air it is weighed and at once suspended in the solution.

As soon as the deposit is made the plates are removed, washed in pure water slightly acidulated, and placed in a tray of distilled water. The deposit on the cathode ought to be firm and even, but if there are any crystals projecting care must be taken not to knock them off in washing. This plate is immediately rinsed, dried as before, and when cool weighed. The gain of metal should exceed a gramme.

Special care is taken in cleaning and washing the cathode, which is the only plate weighed. The loss of weight by the anode is usually greater than the gain by the cathode, the difference going to strengthen the solution. Unfortunately the loss is too irregular to be used even as a check.

The solution should be of pure, or good, commercial copper sulphate, free from iron, and have a density anywhere between 1.08 and 1.18. Three to five parts by volume of concentrated solution (density, 1.21) to one of clean water are recommended, with one per cent. sulphuric acid added if the solution is not sufficiently acid from the salt. There should be three cubic centimetres of liquid for every square centimetre of surface—counting one side of all the plates—and it may be used ten hours before throwing away. If the density is much less than 1.08 the deposit is less adherent, and if greater than 1.18 there is danger of the solution becoming saturated, causing, in the first place, oxidation which increases the gain of the cathode and, secondly, the formation of sharp crystals at the edges.



The solution must be kept distinctly acid to retard its action on the plates. It is found that copper metal in the sulphate solution loses and, sometimes by oxidation, gains weight in an irregular way. The action appears to be greater when a current is passing; it is slightly less for densities between 1.10 and 1.15, but never wholly ceases, and with acid present it may amount to $\frac{1}{500}$ of a milligramme per square centimetre per hour. The error from this source will not exceed $\frac{1}{50}$ of one per cent. The objections made against the copper voltameter have been this uncertain loss of plate in the solution, and its tendency to oxidize after it is withdrawn and before it is weighed.

The results of many experiments indicate the best size of cathode to be that which presents about 100 square centimetres to every two amperes, or at that rate. In other words, the current density should be about .02. It may be as high as .02½, but if it much exceeds this figure there is liability of sharp crystals forming on the

edges after 20 or 30 minutes, a weakening of the solution next the anodes and fluctuation of current from temporary polarization. With diminished current, as low as .003, the deposit is firm and even, but slightly less than it ought to be. It may, therefore, be used if we take a number smaller than the electro-chemical equivalent for a divisor, as shown in the table. The objection to small current density is that it increases the relative amount of error due to the action of the solution on the plates, leakage between the plates, oxidation of deposit after its removal from the bath, errors of weighing, and so on.

Increase of temperature is likewise found to diminish the proper gain of weight by the cathode, and correction is made as above by taking a smaller number for the equivalent from the table. The effect is slight for changes at ordinary temperatures and greater at 30° or 35° C.

The rule for getting the current strength in amperes, then, is to divide the weight in grammes deposited in one second of time by .0003287 when the density of the solution is between 1.08 and 1.18, the current density about .02 and the temperature about 12° C. For other densities and temperatures take the divisor from the following table, given by Mr. Thomas Gray, to whom and to Dr. Kittler we are indebted for the development of the copper voltameter as a means of calibrating current measuring instruments:

TABLE.

Sq. cms. of cathode per ampere.	Current Density.	2°C.	12°C.	23°C.	28°C	35°C.
50	.02	.0003288	.0003287	.0003286	.0003286	.0003282
100	.01	8	84	83	81	74
150	.006⅔	7	81	80	78	67
200	.005	5	79	77	74	59
250	.004	3	78	75	68	52
300	.003	2	78	72	62	45

If the voltameter is suited to the current strength, or can be adjusted to it by changing the size or number of plates, it is joined in simple series circuit with the galvanometer to be calibrated, a mercury key, a small extra resistance, and a constant battery. The extra resistance which may consist of a strand of wire on two rollers, as in the Thomson pattern, or of this rheostat joined in parallel with a few coils, is intended to keep the current uniform by more or less of it being thrown in or removed from the circuit. If the current is small, tray cells in series furnishes a steady current, and a high electromotive force is desirable. In case of large currents, accumulators are usually employed. We can previously determine the number of cells and the best method of grouping to give the necessary current with a portion of the extra resistance in circuit. The voltameter resistance will be about 25 ohms divided by the number of square cms. on one side of the cathode.

If the voltameter is for small and the galvanometer for large currents, the circuit is arranged as in the diagram.

R and *r* are straight german silver or platinoid wires or strip, eleven for example, having equal resistance, and connecting the heavy copper blocks *b*, B and B′. One or more of the wires terminating in B may be shifted to *b* as required. Blocks, *b* and B, are connected by a sensitive zero galvanometer, *g*, some distance away to indicate whether or not they are at the same potential. If they are not, the potential of *b* is adjusted to that of B by means of the rheostat, *r*, next the voltameter, *v*. B′ is a heavy current resistance for adjusting the galvanometer G (to be calibrated) to the required deflection. Accumulators, A, supply the current. With ten wires in R and one in *r* and *b* and B at the same potential, the current through G will be ten times that passing through the voltameter.

If the voltameter is for large and the galvanometer for small currents, G and *v* in the diagram replace each other; or the "shunt" arrangement (shown in the January number of this journal, 1885) may be used.

The operation is sometimes begun with a trial deposit, lasting a few minutes. The cleaned plates are suspended in the solution, and the current adjusted to the proper strength by means of the extra resistance or subsequent change in the battery. The cathode is taken out—the circuit, exclusive of the voltameter, being kept closed in order that it may remain warm. If the small deposit is found to be firm and uniform on both sides, the plate has been properly cleaned and is in good condition to receive the regular deposit. It is then rinsed, dried and weighed as described and replaced. If the plates are large it may be necessary to put glass rods vertically between them to keep from touching each other. The circuit is closed and the time of closing noted. The needle is closely watched, and the current kept steady during the time of deposit which, as a rule, will be an hour or more. The time of opening the circuit is observed when the plates are taken out, the cathode washed and weighed as soon as it is thoroughly dried.

Large crystals on the edge indicate too great density of solution or current or both. If the deposit has a dark color there was too little acid, and the gain of weight is too large.

It is easy to obtain a uniform and solid copper deposit, and if pains be taken to keep the bath acid, to clean the plates thoroughly before deposition, and after it to wash off the solution promptly and to dry the plates well before weighing, accordant results will be obtained.

PATENTS IN THE COURTS.

BY GEORGE H. STOCKBRIDGE.

WHEN President Cleveland was making his selections of the various heads of departments and bureau officers, he was reported to have stated that he especially desired to secure an efficient Commissioner of Patents, as he had heard more complaint about the Patent Office than about any other bureau under the government. One can easily believe this report to be true in view of the severe criticisms which have been circulated of late years both in and out of the public press relative to the conduct of affairs in the Patent Office. Critics of our patent system, however, and of the manner in which it is administered, should first of all be sure of their facts. This is certainly not too much to demand, though it is more than has generally been accorded. One of the current misstatements regarding patents was touched upon in a previous article.[1] It was found that, whereas it had been charged that nine patents out of every ten are shown to be worthless under test, the facts go to prove that about seven out of every ten are judicially sustained. The figures as I gave them in my previous article made it appear that the ratio of patents sustained to those vacated is about six and a half to three and a half. I mentioned, however, the fact that the true ratio was reduced by the inclusion of reissue patents, which, since 1882, had been uniformly vacated. The reduction due to this cause is amply sufficient to make the basis of reckoning seven to three as between sustained and vacated original patents, and I shall hereafter employ that ratio as fairly indicating the facts in the case. Starting from this point, then, and before making even this showing the basis of a criticism of our patent system, as some might be inclined to do, a proper subject of inquiry still is, how far is the Patent Office responsible for the fact that not *every* patent is found to be valid when it comes to be judicially passed upon. This question will be determined most readily by considering to what tests patents are subjected. The five grounds for the setting aside of a patent are set forth in section 4,920 of the revised statutes, as follows:—

In any action for infringement the defendant may plead the general issue, and having given notice in writing to the plaintiff

1. See the *Electrical World*, New York, April 30, 1887.

or his attorney, 30 days before, may prove, on trial, any one or more of the following special matters:—

First.—That for the purpose of deceiving the public the description and specification filed by the patentee in the Patent Office was made to contain less than the whole truth relative to his invention or discovery, or more than is necessary to produce the desired effect; or,

Second.—That he had surreptitiously or unjustly obtained the patent for that which was in fact invented by another, who was using reasonable diligence in adapting or perfecting the same; or,

Third.—That it has been patented or described in some printed publication prior to his supposed invention or discovery thereof; or,

Fourth.—That he was not the original or first inventor or discoverer of any material or substantial part of the thing patented: or,

Fifth.—That it had been in public use or on sale in this country for more than two years before his application for a patent, or had been abandoned to the public.

The law provides, then, among other things (sec. 4,920, article 2), that a defendant in action for an infringement "may prove that the patentee had surreptitiously or unjustly obtained the patent for that which was in fact invented by another, who was using reasonable diligence in adapting and perfecting the same." If this is proved the patent will be declared invalid. From the nature of the case, however, it is apparent that the Patent Office has no means of knowing whether or not anyone is using reasonable diligence in adapting and perfecting an invention for which it is solicited to grant a patent. All the proof on that point is naturally brought out in the court proceedings and nowhere else. It would certainly be unfair to charge the Patent Office with responsibility for the invalidity of this class of patents.

The defendant may also prove (art. 5) that the invention "had been in public use or on sale in this country for more than two years before the patentee's application for a patent, or had been abandoned to the public." These are also matters of fact of which the Patent Office cannot reasonably be expected to be cognizant except in notorious cases. The Patent Office is not chargeable with fault, when patents are found to be invalid on the grounds just mentioned.

In the first, third and fourth articles of section 4,920, we touch upon matters for which the Patent Office may be fairly held responsible, although not wholly so as respects the fourth proof, inasmuch as the evidence showing that the patentee "was not the original and first inventor or discoverer of any material and substantial part of the thing patented" may rest upon facts of which the Patent Office could know nothing.

The first ground for the vacating of a patent is that, for the purpose of deceiving the public, the description and specification filed by the patentee in the Patent Office "was made to contain less than the whole truth relative to his invention or discovery, or more than is necessary to produce the desired effect." This is a matter which it devolves upon the Patent Office to see to. When a patentee who has taken out a U. S. patent in good faith has it declared void by the courts on either of the grounds above recited, he has a right to complain that the Patent Office has failed in its duty. It is the function of the office to see that neither the inventor nor his attorney mislead the public intentionally or inadvertently either by stating too much or too little. As a matter of fact, however, very few patents are vacated by reason of insufficient or over-sufficient specification. Practically those items can be left out of account altogether without substantially changing the result.

The great mass of vacated patents are declared invalid on the other proof above mentioned, and respecting which we have seen that the Patent Office has little or no responsibility, or upon the third proof, namely, that the invention "had been patented or described in some printed publication prior to the patentee's supposed invention or discovery thereof." Probably two-thirds of all patents vacated—that is, two patents out of every ten—are vacated on this ground. Regarding this article of the statute, the Patent Office is wholly responsible. Nevertheless, I wish to call attention to certain matters, which, while they do not excuse it, explain the fact that a large number of patents are vacated under this clause.

Take, for example, the class of electricity. Prior to July 1, 1881, there had been issued 3,875 electrical patents. Since that date electrical inventions have been patented at the rate of about 1,100 a year. By the first of July, 1889, there will have been issued in this country not far from 13,000 electrical patents. I do not know the exact number of English patents in electricity, but I suppose thay will by that time reach 7,000. For another estimate, I should say that there will be 4,000 German electrical patents and 2,000 French. Italian and other patents are not often referred to. Besides these, there are many books on electrical subjects which disclose matters not covered by patents in any country.

Now, in making searches on electrical applications, the examiners in the electrical divisions of the United States Patent Office have to search through all these various publications and that, too, with the utmost care and attention. No one who has tried it himself, with the limited time given for each examination, will wonder that two patents out of every ten are found to be broader than they ought to have been in view of references which the office overlooked.

It is not, of course, true that every time an application is examined this whole matter has to be gone over, but a dozen applications in as many different sub-classes might lead the examiners through a large portion of it. To make clear exactly what I mean, let me suppose that an inventor puts in the first day of next July an application for a patent on a dynamo-electric machine. In making his search the examiner may have to look through all the patents in the classes of "magneto-electric" "motors," and possibly "regulators," and several other sub-classes. Estimating in accordance with the number of patents in these classes down to July, 1881, and proportionately in accordance with the increase between that date and July, 1887, when the last index of electrical patents was published, the examiner will have about 1,200 United States patents to examine. If the British, French and German patents on dynamo machines and allied inventions cover the same proportionate number as do the American patents on those devices, he will also have to examine some 600 English patents, 200 French patents and 400 German. Besides, he will probably be required to examine two or three volumes devoted specifically to the dynamo machine and other volumes on general electrical subjects. If the examiner had unlimited time to devote to the subject, he would doubtless be reasonably sure, when he had ended, that nothing had been overlooked. Even then, mistakes and oversights would sometimes take place. But it must be remembered that the average time which an examiner can devote to each new application is not over half a day, though, on an invention of such importance as a dynamo-electric machine, we will give him a full day's search. Does anybody wonder that mistakes are made or, rather, does not everybody wonder that they are made so rarely?

The only foreign patent office that makes a search at all comparable to ours is the German. The German patent system, modeled after ours in nearly every particular, lays even greater stress upon the thoroughness of the search. Up to within a short time the German government printed upon the face of the patents issued under its seal a guarantee of its validity. I observe that this guarantee no longer appears on German patents; presumably because it has been found impossible to make the searches so careful and far-reaching as to leave no room for oversight. In this country, the oversights occur in two cases out of ten.

After what has been said above, it is not believed that anyone will be inclined to think me guilty of an overstatement in my former article, where I said that the statistical showing regarding sustained and vacated United States

patents is creditable to the Patent Office. Absolutely and in the abstract it may not be creditable; but it is creditable when the circumstances above recited are considered. The only way to improve the present condition of affairs is to alter the circumstances. If any administration wishes to reduce the amount of just criticism against the Patent Office, there is one way to accomplish it, and that is to do what every commissioner of patents for the last 30 years has been urging; to wit, increase the examining force and their salaries and facilities for work. No amount of executive ability in the commissioner can add authority to Patent Office examinations, so long as each examiner has to make searches on more than thirty new applications a month and keep up besides with an accumulating mass of amended work.

I am aware that some of the loudest complaints against the Patent Office are based upon the fact that the examinations are slow, a fact which is easily accounted for in view of what has been said above. Such complaints are well founded and deserve consideration; but the only criticisms, after all, which can ultimately redound to the discredit of the Patent Office are those which affect the authority of its examinations. A loss of confidence in the faithfulness and approximate reliability of the official searches would, in the end, destroy the patent system. No matter how slow the search is, within any reasonable limits, if only the proprietors of patents may feel confident that they have something upon which they can safely build. The efforts of various commissioners of patents to increase the rapidity of examinations have invariably resulted in cheapening the quality of the office work. What is needed is a force large enough to give a reasonable time to each search and skilled enough to know its business, and with room enough to do its work to advantage, and, until that is provided, it will be useless to expect a better showing for patents in the court records. More men, salaries high enough to keep the good ones, and room for them to work, will go far toward solving the problem

PHYSICS-TEACHING.

REPORT OF THE COMMITTEE, OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, ON PHYSICS-TEACHING.

Presented to the Council of the A. A. A. S., at the Cleveland meeting, August, 1888.

At the Philadelphia meeting of the association in 1884 the undersigned were appointed a committee to consider and report upon the subject of physics-teaching.

Brief reports of progress were made at the various meetings since that date, but it is only within the past year that the committee has been able to formulate and agree upon a final report which it now offers to the association through the council, at the same time respectfully requesting that it be discharged.

Before entering upon the consideration of the report, it seems proper to refer to some of the causes which have led to so long a delay in its preparation. Shortly after the appointment of your committee, consultation and correspondence with persons interested in the subject developed the great desirability of securing, if possible, the coöperation of the National Educational Association, many of the members of which were more deeply interested, if possible, in certain phases of the subject to be considered, than the members of our own body. In accordance with this idea the council of that association, at its meeting in 1885, appointed a committee on physics-teaching, consisting of Charles K. Wead, LeRoy C. Cooley, W. LeConte Stevens, W. F. Bradbury and James H. Baker.

This committee was not appointed for the specific purpose of coöperating with that of the A. A. A. S. in the preparation of a joint report, but an effort was made by the respective chairmen to secure a joint meeting of the two committees for this purpose.

This effort failed on account of the wide geographical distribution of the members. The committee of the National Educational Association prepared its report, however, and it was presented at the meeting of that body in 1887. It is probably well known to those who have especially interested themselves in this matter. An attempt was made to secure a meeting of your committee at Buffalo during the meeting of the association in that city in 1886. A majority of the committee was present and an informal discussion of the subject was had, but it was thought best to defer any report until a full meeting could be held.

Accordingly a meeting was called at Washington, D. C., in December, 1887, and at this meeting, the first session of which was on December 24, all of the members of the committee were present except Professor Trowbridge, who found it impossible to attend.

At this meeting the subject was fully discussed and it was found that the members present were substantially in agreement as to the principal questions involved.

In presenting the conclusions reached it is not thought to be necessary or desirable to insist upon the importance of the study of physics or to offer arguments in favor of its introduction. This ground has been gone over so often and so thoroughly within the past decade that further discussion seems unnecessary.

As a matter of fact it may be said that nearly everything which can be justly claimed is now nearly everywhere admitted. Neither has it been thought necessary to go into detail as to methods of instruction.

The publication in the English language within a few years, of several excellent text-books of physics and a few laboratory guides of a high order of merit, together with a considerable advance in real scholarship among teachers, make it possible to use the phrases "text-book work," "lecture work" and "laboratory practice" with a fair chance of being understood; yet it may be well to remark that where the latter is referred to, something very different from mere illustrative experimentation is meant, it being the opinion of the committee that the work in the laboratory should be quantitative rather than qualitative, and always of as high a degree of precision as is possible with the appliances available.

In order to give definiteness to its conclusions the committee undertook to answer the following questions:—

1. In what grade of the public school should physics-teaching begin?

2. What should be the character of this first instruction? oral? By text-book? By laboratory methods? etc.

3. What should be the character of the physics-teaching in the high school? Text-book? Laboratory? Text-book followed by laboratory? Laboratory followed by text-book? or, Laboratory and text-book combined?

4. What knowledge of physics should be required for admission to college?

5. What should be the minimum course in physics for under-graduate students, and what should be the nature of this course?

In answering these questions the needs of special students, or the requirements of scientific and technical schools and courses have not been considered. It may be fairly assumed that such students and courses and schools will take care of themselves.

The conclusions reached have reference only to the minimum training allowable in a course of study so adjusted as to give the student what we may continue to call, for want of a better name, "a liberal education."

1. In answer to the first question, it is the opinion of the committee that instruction in physics may begin, with profit, in what is generally known as the "grammar school." At the same time it is decidedly opposed to any general recommendation that it must begin there or in the primary school. Here, perhaps more than anywhere else, nearly everything depends on the teacher. One who has

a strong liking for and a good knowledge of physics will be tolerably certain to succeed, while another not thus equipped for the work is equally certain to fail. Teachers belonging to the first class constitute an extremely small percentage of the grand total. In science-teaching in grades below the high school, much should be left to the individuality of the teacher. As a result of personal taste or previous training and study, one may give elementary instruction in botany, or in geology or in physiology so as to be a real inspiration to his class, while his instruction in physics might be so intolerably poor as to be unprofitable in the highest degree. The prevailing custom of many public schools which requires all teachers of a certain grade to teach physics is greatly to be regretted, and every effort should be made to show school superintendents that it is a mistake which cannot be too quickly remedied.

The rapid advancement which is constantly being made in real scholarship among public school teachers will result in an increased and increasing number of those who are competent to teach physics; and while the committee is convinced that, as a means of real, honest, mental discipline, no branch of natural science is superior to physics, it would deprecate its forced introduction into the grammar school under circumstances likely to prove disastrous to the best interests of the science.

2. When taught in the grammar school, and by a competent teacher, it should be done mainly by and through illustrative experiments.

These may be of the simplest character, involving and exhibiting some of the fundamental principles of the science, and they should generally be made by the teacher, the pupil being encouraged to repeat, to vary and to extend. Habits of observation and of thought should be cultivated, and such facts of the science as are based on or relate to the principles illustrated and developed should be presented. It is neither desirable nor necessary that any particular order should be followed in presenting the various divisions of the subject. The teacher should be guided by circumstances, such as the means at his disposal for experiment and illustration, and often by his own taste and predilection.

The ease with which apparatus for the illustration of the most important principles of physics can be improvised, even when the stock of materials at hand is very slender, puts the science in the front rank as to availability, and it is especially adapted to the requirements of certain schools both in town and country which, through their situation and surroundings, are restricted in their choice of a science subject. If to these facts we add another, which is universally admitted, that the physical properties of matter are the first to be recognized, the laws relating to which being, therefore, the first to arrest attention, it needs no argument to show that a competent instructor will find the study of physics one of the most important educational forces, even in the grammar school.

3. In any discussion of the character of instruction in physics in the high school, one fact of the utmost importance must not be lost sight of. It is that a large majority of the young people who are educated in the public schools receive their final scholastic training in the high school.

Its course of study must be in harmony with this fact, such provision as may be made for those who continue their studies in college or university, being merely incidental.

The high school course in physics must include therefore a general treatment, which must of necessity be elementary in its character, of all the great divisions of the science.

It is likewise important that the student should be made acquainted, if only to a limited extent, with the methods of physical investigation and that he should be able himself to plan and carry out an attack upon some of the simpler problems of the science. The value of this work as an educational factor cannot be overestimated; it is the "walking alone" of intellectual infancy.

It is believed that these two very desirable ends can be reached without giving an undue share of the time and energy of the pupil to the subject. Assuming the high school course to consist of four years of three terms each, it is recommended that the study of physics should begin not earlier than with the third year; that it should continue through one year, three hours a week being devoted to it, not including the time necessary for the preparation of the lesson; and that during the first two terms the work should be text-book work, accompanied by illustrative experiments performed by the instructor and made as complete as his facilities will allow, while the last term should be devoted to simple laboratory exercises. It is hardly necessary to say that during the last term the three hours per week should be grouped into one exercise whenever possible.

Of the character of this laboratory practice it may be well to say that no attempt should be made to carry the pupil through a very great range of subjects. The end sought for can best be reached by a careful and more exhaustive study of a few problems which should be solved with the highest degree of accuracy attainable under the circumstances. As far as possible the pupil should be led to read and study books and papers bearing upon the particular subject which he has in hand. The time demanded by this plan, three hours per week for one school year, barely more than a hundred hours in all, is thought to be the least which is likely to produce results at all satisfactory, and it is urged that a vastly better arrangement is to allow the study of physics to run through two school years, giving it in time, the equivalent of five hours per week for one year.

It is well known that many teachers of physics, and many more who are not teachers of physics, insist on the introduction of laboratory practice from the beginning, some even going so far as to claim that the use of the text-book may be entirely dispensed with. Without desiring to enter into a discussion of this question, we wish to express and with emphasis, our belief that laboratory practice is in general of little real use to the student unless he comes to it fairly well grounded in the fundamental principles of the science. The somewhat widespread opinion and practice, to the contrary, will be found, it is thought, to be one of those mistakes in which pedagogics seems to be caught on the rebound from other and generally more serious errors.

4. As to the requirements in physics for admission to college, it is sufficient to say that the course indicated above should be required for admission to any and all courses in the college.

5. In reference to the minimum course in physics for under-graduate students in the college, it seems important to avoid the mistake of asking too much.

In many institutions, and especially where the elective system largely prevails, it is possible at present for students to receive a degree and yet be almost absolutely ignorant of the principles of physics. It is the judgment of the committee that a knowledge of this subject constitutes one of the necessary and essential elements of a liberal education, and a minimum course of three hours per week for one year is recommended. What is usually known as the junior year is most desirable for this work, as at that time the student is sufficiently mature and has acquired the necessary training in mathematics to enable him to make the best of what he does. It is recommended that this course consist entirely of text-book and recitation work, with lectures fully and completely illustrated on the professor's table.

It may possibly excite surprise that laboratory practice is omitted, but it will be remembered that this is a minimum course, in which it is not believed that the laboratory can be made to play a useful part. Whenever it is possible to increase the time devoted to the subject, this course may be and will be followed by a series of laboratory

exercises. The nature of these must depend almost entirely on the skill and judgment of the professor in charge and on the facilities which he is able to command.

In any event it should be his aim to attend rather to quality than to quantity of work, and it should not be considered necessary for each student to work in or even to touch *all* of the great divisions of the subject.

In conclusion, your committee believes that whenever the association speaks and in whatever it may say upon a subject so important as that under consideration, it should be governed by a wise conservatism, and that it should keep always in view the fact that when its suggestions and recommendations are in the real interests of the school and the college they are certain to be in the line of the advancement of science.

PRACTICAL NOTES CONCERNING THE CONSTRUCTION, USE AND MANAGEMENT OF STORAGE BATTERIES.

BY A. RECKENZAUN.

(Continued from page 394, vol. vi.)

PROPELLING ELECTRIC LAUNCHES.

MUCH has been written and said about the adaptability of storage batteries to purposes of marine propulsion; nevertheless the question of weight of the battery is continually being reopened by persons interested in the subject. The hopes which were entertained a few years ago, and which still fondly cling to the breast of amateurs, that "some day" we shall have storage batteries of very light weight compared with great power, are gradually being dispelled. Structurally, secondary batteries have been much improved since the first electric launch made its appearance; but the attempts to reduce weight have failed, and it is admitted by all who give the subject serious consideration that the present most successful combinations have been determined after much practice, from which it is difficult to deviate without sacrificing some essential quality. For special purposes, where first cost and depreciation do not enter into calculations, we may yet wring a morsel from the possibilities which nature provides.

Theoretically, a comparatively large amount of energy is manifested in the separation of metallic lead from its oxide. According to Professor Reynolds, it equals 360,000 foot pounds per pound of lead acted upon, if every atom could be brought under the influence of chemical action. But in secondary batteries we cannot use the material in such a finely divided state; we require a support, which must also be a conductor, and this, with the acid and a suitable receptacle, brings the weight up to over 10 times the value given in chemical equivalents. Several years practical experience point to the conclusion that secondary batteries of sufficient mechanical strength and durability cannot yield much more than seven watt-hours per pound weight of material. This includes plates made of lead and oxides of lead, acid, cell and terminals; and these figures are based on the assumption that the rate of discharge does not exceed three-quarters of an ampere per pound of accumulator, or, approximately, one ampere per pound of plate. At this rate it is possible to maintain an average E. M. F. of at least 1.87 volts per cell for the entire useful discharge period.

A pleasure launch of 30 feet length, 6 feet beam and 2 feet draught of water can be driven at a speed of from six to seven miles an hour in still water, with an expenditure of about 3,000 watts, through an efficient motor actuating an efficient screw propeller. A continuous run for six hours would thus necessitate a battery of 2,571 pounds weight, consisting of 60 cells, if each were to weigh 43 pounds.

Seven miles an hour may be considered a moderate speed. It is, of course, possible to travel much faster than this, but at an enormous sacrifice of energy. Each additional mile involves an increase of power altogether out of proportion to the gain in speed. To illustrate this we may cite an example from carefully conducted speed trials on the measured mile at Long Reach, in April, 1886, under the auspices of Messrs. Yarrow & Co. and the naval attachés of the Italian government. The launch in question was built of steel on the most approved lines; it was 36 feet long and of 6 feet beam; her storage battery consisted of 73 cells. With 53 cells in circuit an average speed of 7.51 miles per hour was attained, and when 20 extra cells were switched into circuit the average speed came to 8.43 miles per hour, showing an increase of only .92 of a mile per hour with 37.7 per cent. more E. M. F. Theoretically, the power required to drive a boat varies as the cube of the speed. Great speed, therefore, can only be obtained with a high current rate, which means a very rapid discharge of the cells and a correspondingly early destruction of the plates. There is scarcely any advantage gained by increasing the size of the battery if the same is already as heavy or heavier than the hull and live load combined; consequently the limit of speed in any electric launch has to be determined by the limit of the current which the accumulator is capable of giving off at any time.

With regard to the space occupied by a lead battery yielding seven watt-hours per pound weight, this we find to be about one cubic foot per 1,000 watt-hours. The cells in the 30 feet boat above referred to, with a capacity of 3,000 watts for six hours would then occupy 18 cubic feet, or if the height of the boxes over all is 1 foot, the necessary floor space must be 18 square feet. Confining ourselves to small vessels, which come under the category of "launches," driven by lead storage batteries, we may safely assert that these can never be propelled at a speed of more than 15 miles an hour, no matter what sacrifice we make; furthermore, it may be stated with equal certainty that the distance that can be traversed with one charge of batteries in still water will not be more than 100 miles, at a speed of not less than four miles an hour. Within these limits, however, there is a fruitful field for further developments, and the steps taken by Messrs. Immisch in establishing charging stations up the river are likely to cause a demand for boats propelled by electric energy.

EFFECT OF SHAPE OF PROPELLER UPON RATE OF DISCHARGE.

One of the most difficult parts of a launch is the screw propeller. Almost any kind of screw will push a vessel through water, but with different samples results of a varying kind may be obtained. In order to ascertain the merits of some, we made a series of experiments, five years ago, with three screw propellers on a small launch. It will be observed that in each experiment there were considerable differences in the current and number of revolutions, although the same battery and motor were used in every case. Each screw had only two blades; the dimensions were as follows, distinguishing them by the letters A, B and C:—

	A	B	C
Diameter in inches	19.875	18.75	17.75
Mean pitch in inches	12.9	12.25	11.5
Disc area of blades, square inches	94	76	59
Whole disc area, square inches	314	276	247
Expanded area of blades, sq. inches	103	82	66

Table xi. gives the mean results of the tests with each screw, and it shows that the work done does not vary in proportion to the energy expended upon it. The relative

work of the screw is assumed as proportional to the number of revolutions, and the relative energy consumed varies with the current.

TABLE XI.

Number of experiment.	Revolutions per minute.	Relative work of screw.	Current in amperes.	No. of cells.	Electrical horse-power.	Relative electric energy.

(To be continued.)

ELECTROLYSIS OF TIN SALTS.[1]

BY ALEXANDER WATT.

ALTHOUGH there have been many attempts to introduce electro-tinning as a branch of the electro-plating industry, the art has not yet attained a high state of development, at least in this country. That electro-tinning is susceptible of many useful applications is beyond doubt, but it is also true that no really good electrolyte has yet been discovered which will enable the depositor to pursue the art with the same facility and comparative certainty with which he can generally conduct the deposition of other metals which receive his daily attention, as gold, silver and nickel, for example. Of the several causes which affect the uniform action of the tinning baths ordinarily applied, the most important are:— 1. That the anode does not dissolve with sufficient rapidity to keep up the normal strength of the solution, which necessitates the frequent addition of tin salt to the electrolyte; consequently the liquid is never in such an uniform condition as to ensure regularity of deposit. 2. That the tin solutions usually employed, being constantly under atmospheric influence, are continually undergoing change of condition, and as a consequence are unreliable. These are serious faults in any electrolyte to be employed for commercial purposes on a large scale, and place the operator at a continual disadvantage, since he can never know to a certainty when his bath may require an addition of tin salt, nor the precise quantity necessary to keep the bath at its normal strength.

Many different salts of tin have from time to time been employed for making up baths for the electro-deposition of the metal for practical purposes, but it is doubtful whether the chemical field has been sufficiently explored to render improvement improbable. With this impression, I carried out a long series of experiments, the results of which will, it is hoped, prove useful to those who may desire to know the behavior of other salts of tin than such as are usually employed for the deposition of the metal, while it is possible that the results I am about to describe may suggest further modifications in the minds of others, and thus tend to the ultimate development of a really good tinning bath, free from the defects to which attention has been called. In conducting the following experiments the Daniell battery was employed, and in most instances the current from a single cell, or about .669 ampere, was found sufficient for the deposition of the metal from most of the electrolytes employed The anode consisted of a stout plate of tin, about three inches square, and the receiving plates were generally strips of sheet brass, three inches long and one inch wide, to each of which a length of copper wire was soldered. Before commencing the various trials, a quantity of the hydrates of protoxide and peroxide of tin was prepared, and after being well washed and drained, the respective oxides were kept in their moist condition for the preparation of tin salts as required.

1. *Protochloride of Tin.*—It is well known that a solution of this salt, when subjected to electrolytic action, deposits metallic tin either in a spongy condition or in the form of crystals, according to the strength or weakness of the electrolyte and the amount of free acid present. When electrolyzing a solution of the protochloride it has frequently been noticed, after the electrodes have been immersed in the bath for a few moments, that bright crystals of metallic tin of a feather like appearance would form upon the surface of the cathode, and eventually spread forwards until they reached the anode, when the current would be short-circuited and the crystals would then drop from the cathode and deposit at the bottom of the vessel. Being anxious to obtain permanent specimens of the beautiful crystals produced from the protochloride solution by electrolysis, I proceeded in the manner described in my former papers on the "Electrolysis of Lead Salts" (*Electrical Review*, April 27th, 1888). A solution was first prepared by dissolving 120 grains of fused protochloride of tin in 16 ounces of water, acidulated with half an ounce of hydrochloric acid. This solution was then filtered and afterwards poured into a flat dish,

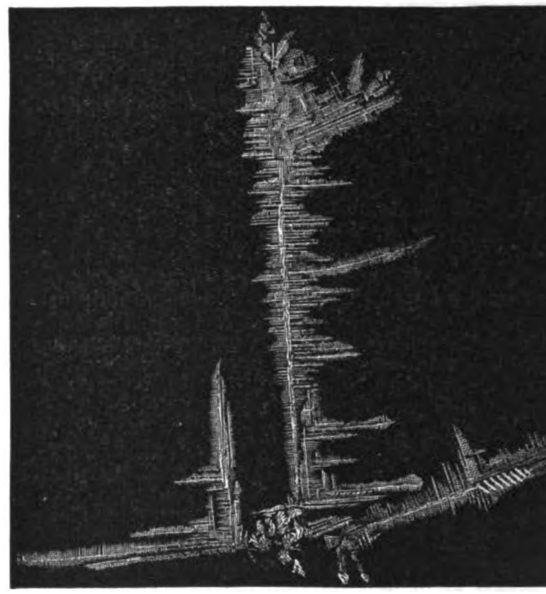

FIG. 1.

on which was laid a plate of glass about seven inches by five inches. A tin anode, connected to the positive pole of a single Daniell cell, was then immersed in the bath and allowed to rest on one end of the glass plate; a narrow strip of sheet brass, slightly curved at its lower end, and with copper wire attached, was used as a cathode, and this being connected to the negative electrode of the battery was next placed upright on the opposite end of the glass plate, when in less than half a minute small fern-like crystals began to form at each corner of the cathode, and gradually extended, radiating in all directions, but chiefly in the direction of the anode, until in the course of about half an hour

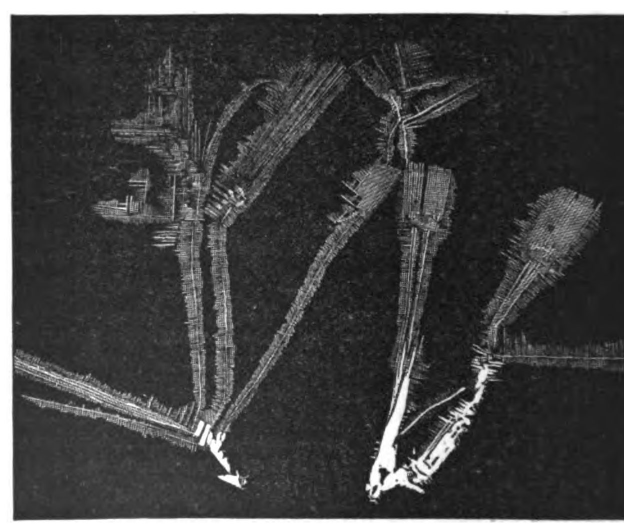

FIG. 2.

they had attained the length of several inches, the crystals lying perfectly flat upon the surface of the glass plate, like seaweed expanded in water, excepting those in immediate contact with the cathode, which accumulated in clusters reaching to the surface of the liquid, which latter covered the plate to the depth of about one-eighth of an inch. In little more than an hour the plate was nearly covered with crystals of most exquisite beauty, but in separate groups, proceeding from the extreme corners of the cathode. It was noticed that as the crystals grew nearer to the

1. From the *Telegraphic Journal and Electrical Review* (London).

anode they extended with greatly increased rapidity; so much so, indeed, as to create some little astonishment, while this rapidity of formation caused the crystalline deposit to become highly attenuated at the extreme points nearest the anode. When the crystals had approached within $\frac{1}{16}$th of an inch of the anode, that electrode was withdrawn, and the crystals then carefully disconnected from the cathode with the blade of a penknife, and the brass plate then removed from the liquid. The solution was then

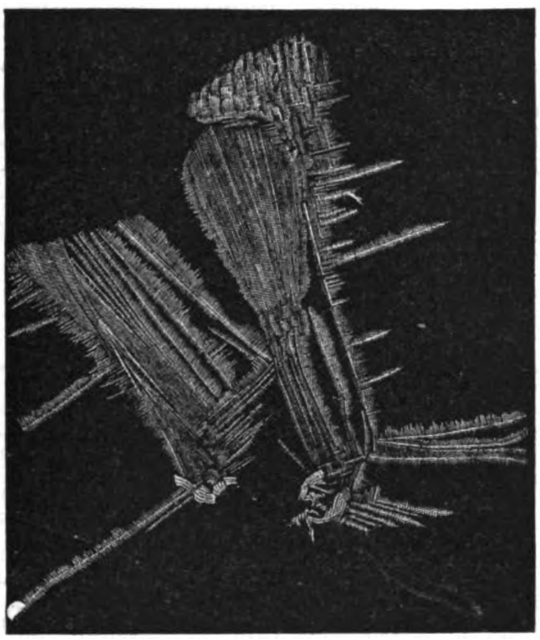

FIG. 8.

carefully and slowly poured out of the dish, and the glass plate bearing the crystals then removed and placed in a nearly upright position upon a pad of blotting paper to drain, after which it was replaced in the dish (which had been previously well rinsed) and water slowly poured in until the plate was well covered, the object being to wash away the adherent tin salt. Portions of the washing water were from time to time withdrawn by means of a pipette, and fresh water applied as before, until the crystals were fairly cleansed from the salt of tin. It should be mentioned that the water used in washing the plate produces a white precipitate, which it is necessary to prevent from settling on the surface of the plate, and this can be effected by the method indicated, but the greatest care is necessary to prevent the fragile deposit from becoming disturbed, in which case it would inevitably float away from the surface of the plate. Instead of pouring off the tin solution when the crystals are obtained, I find it a better plan to gently raise the glass plate at one end with the first finger and thumb of each hand, and finally rest it on one corner until the greater portion of the liquid has drained from it into the dish; it is then placed on a pad of blotting paper as before mentioned. It is important to bear in mind that if the tin salt surrounding the crystals is not removed by washing, the delicate crystals are apt to become partially redissolved, while the salt will also crystallize in drying, and thus destroy the beauty of the result. When the plate has been sufficiently washed, it is gently removed from the dish and drained as before, and may then be put in a warm place or held before the fire until dry. It should next be coated with a thin varnish—ordinary photographic varnish is most suitable—which should be applied by pouring it in the centre of the plate, and allowing it to flow towards each corner, finally tilting the glass to allow the surplus varnish to return to the bottle. Before and after applying the varnish, the plate should be slightly warmed by holding it at a short distance from the fire.

Having now protected the tin crystals by a coating of varnish, we may next proceed to obtain reproductions or prints from them in the same way as ordinary photographic pictures are obtained, by treating the glass plate bearing the crystals in all respects as a photographic "negative." The plate being placed in a suitable printing frame, with the crystals upward, a piece of sensitized albumenized paper is laid on the face of the plate, and over this several folds of blotting paper. The shutter of the frame is then adjusted in the usual manner, and the frame exposed to the action of sunlight until all the details of the crystals are fully impressed upon the sensitized paper. The print is then withdrawn, and it is afterwards fixed, toned and washed in the usual way, and after being allowed to dry, may be mounted on a suitable card. In the accompanying illustrations several examples are shown of impressions, taken by the photographic method, of tin crystals produced with solutions of the protosalt of tin at various degrees of concentration, and it will be observed how greatly the forms of the crystals are modified by increasing or diminishing the metallic strength of the tin bath, and also by changing the form of the cathode. In figure 1 the crystals were produced in a solution containing 7½ grains of fused chloride to each ounce of water, moderately acidulated with hydochloric acid, the cathode employed being stout copper wire of about one-fourth inch thickness. Figure 2 represents crystals obtained in the same bath, with a brass cathode about one-half inch wide. In figure 3 the crystals were obtained in the above solution, with a cathode turned up into a semi-circular form, the corners facing the anode.

(*To be continued.*)

THE MINIMUM POINT OF CHANGE OF POTENTIAL OF A VOLTAIC COUPLE.[1]

BY DR. G. GORE, F.R.S.

IN this communication is described the following very simple method of detecting the influence of the minimum proportion of chlorine or other soluble substance, etc., upon the electromotive force of a voltaic couple (*Nature*, vol. xxviii, p. 117).

Take a voltaic couple, composed of an unamalgamated strip of zinc or magnesium (the latter is usually the most sensitive), and a small sheet of platinum, immersed in distilled water, balance its electric potential through an ordinary galvanometer of about 100 ohms resistance by that of a precisely similar couple, composed of portions of the same specimens of the same metals, immersed the same moment as the other pair in a separate quantity of the same water, and gradually add to one of the two cells sufficiently small and known quantities of an adequately weak solution of known strength in a portion of the same water, of the substance to be used, until the balance is upset, and take note of the proportions of the substance and of the water then contained in that cell. In the present experiment a magnesium-platinum couple was employed.

The minimum proportions required with several substances were as follows:—potassic chloride, between 1 part in 3875 and 4650 parts of water; potassic chlorate, between 1 in 4650 and 5166; hydrochloric acid, between 1 in 516,666 and 664,285; and with chlorine between 1 in 15,656,500,000 and 19,565,210,000.

The proportion required of each different substance is dependent upon very simple conditions, viz., unchanged composition of the voltaic couple, a uniform temperature, and employing the same galvanometer. The apparently constant numbers thus obtained may probably be used as tests of the purity or of the uniformity of composition of dissolved substances.

The "minimum point" varies with—1st, the chemical composition of the liquid; 2d, the kind of positive metal; 3d, to a less degree with the kind of the negative metal; 4th, the temperature at the surface of the positive metal, and at that of the negative one; and 5th, with the kind of galvanometer employed.

The order of the degree of sensitiveness is manifestly related to that of the degree of free chemical energy of the liquid, also to the atomic and molecular weights of the dissolved substances, and to the ordinary chemical groups of halogens. The greater the degree of free chemical energy of the dissolved substance and the greater its action upon the positive metal, the smaller the proportion of it required to change the potential.

As the "minimum point" of a chemically active substance dissolved in water is usually much altered by adding almost any soluble substance to the mixture, measurements of that point in a number of liquids at a given temperature with the same voltaic pair and galvanometer will probably throw some light upon the degree of chemical freedom of substances dissolved in water.

POINTERS.

.... MAN is an animal in body, stomach, and legs; but then he is an animal with opinion, and forever he has been systematizing these opinions into philosophies. In the early philosophy everything was endowed with life—and deified—stones, trees, fountains, forests, beasts, winds, waves and stars; and the mysteries of the universe was explained by making all these things intelligent actors. From this, the earliest philosophy of the lowest savage, it is a long way to the philosophy of science, and there have been many stages.—*Major J. W. Powell.*

.... IT seems odd that a judge who decides that the conversion of high into low tension currents and *vice versa* by means of induction coils was common knowledge at the time of Gaulard and Gibbs' patent should decide that there is any invention in the method of connecting up these apparatus in series and that those who employ them in parallel do not infringe. The coupling up of any or *all* electrical apparatus, whether in series or parallel, was common knowledge many years before Gaulard and Gibbs or Zipernowski-Deri were ever heard of.—*Foreign paper.*

PAPERS READ BEFORE THE NATIONAL TELEPHONE ASSOCIATION, NEW YORK, SEPTEMBER 4 AND 5, 1888.

NOTES ON TELEPHONE BATTERIES.

BY F. A. PICKERNELL.

I SHALL not attempt, in these notes, to recommend or describe any particular battery, but shall content myself with pointing out defects existing in the batteries now commonly used for transmitters, and emphasizing the importance of certain features which all telephone batteries ought to possess.

The selection of batteries for transmitters has always been a matter of considerable importance, although not always recognized as such. When the battery transmitter was first introduced, nearly all telephone wires ran on overhead structures, no cables being used. The retardation in these circuits was consequently slight, and it was during this period of the business that the large margin in transmission was observed, it having been found possible to talk with the same ease over circuits fifty miles long as it had previously been over circuits a mile long. This led naturally to poor construction, lines being built with small gauge iron and steel wire, and in many cases without insulators. Such construction cut down this margin of transmission to such an extent that it was found impossible to talk over such lines in bad weather, unless the transmitter and battery were in the very best condition.

Better construction followed, and with better construction the battery problem was of less importance. More recently, however, the extensive introduction of cables has again cut down the margin of transmission. This of course renders it necessary to keep the transmitter and its battery in better condition. As the cable system of any telephone exchange increases, in a like ratio will the importance of the battery problem increase. It was only last week that a gentleman was telling me of his experience in confirmation of this. His company had a cable two and a half miles long which not only had a high electrostatic capacity but also a high resistance. This cable was used mainly for trunk wires. It was noticed that many subscribers who had no difficulty in talking with parties in their own exchange, had considerable difficulty in talking with parties in the other exchanges connected through this cable. Upon inspection it was found that invariably a poor battery was found at the subscriber's instrument. This cable made a very good battery inspector and one, I may say, that did not ruin the transmitter in inspecting.

The battery most commonly used for transmitters is of the Leclanché form. The little attention required by a battery of this class, its freedom from violent acids, the ease with which it is set up, its small consumption of zinc, there being no consumption when the battery is on open circuit, all unite in making it the leading form of telephone battery. However, it polarizes rapidly, and has a high and constantly increasing internal resistance when worked over a low resistance circuit, as it invariably is when used for transmitters. The importance of low battery resistance is shown clearly by the following considerations.

The efficiency of any transmitter, other things being equal, is proportional to the variation in current strength produced in its primary circuit, the greater the variation in current strength the greater being the efficiency. The variation in current strength being proportional to the variation in resistance, it follows that the efficiency of any transmitter is proportional to the variation of resistance produced in its primary circuit. The following table, calculated for a Blake transmitter, shows how important is the part battery resistance plays in modifying this variation in resistance, in other words, in modifying the efficiency of the Blake transmitter

This table assumes the variations in a Blake transmitter to be from 5 to 15 ohms, these figures being the result of many measurements.

Table for Blake transmitters. Resistance of primary circuit of induction coil .5 ohms.

Battery resistance.	Minimum resistance.	Maximum resistance.	Ratio of min. to max.	Percent'ge decrease of ratio from that of battery of no resistance.
.0	5.50	15.50	1:2.82	
.33	5.83	15.83	1:2.72	3.5
.67	6.17	16.17	1:2.62	7.1
1.00	6.50	16.50	1:2.54	9.9
1.33	6.83	16.83	1:2.46	12.8
1.67	7.17	17.17	1:2.39	15.2
2.00	7.50	17.50	1:2.33	17.4

Two ohms is not an uncommonly high resistance for Leclanché batteries, and from the table we see that the variation from its minimum resistance to the maximum resistance of the primary circuit of a Blake transmitter decreases from a ratio of 1:2.72 in the case of a battery of .33 ohms internal resistance to a ratio of 1:2.33 in the case of a battery of 2 ohms resistance, a decrease of 14 per cent.

With long-distance transmitters the battery resistance is an even more important factor, as will be seen by the following table. This calculation for long-distance transmitter assumes variation in resistance to be from 4 ohms to 20 ohms; resistance of primary of induction coil .45 ohms. Three cells of Leclanché batteries are generally used with this transmitter.

Battery resistance.	Minimum resistance.	Maximum resistance.	Ratio of min. to max.	Percent'ge decrease of ratio from that of battery of no resistance.
.0	4.45	20.45	1:4.60	
.33	5.45	21.45	1:3.94	14.
.67	6.45	22.45	1:3.48	24.
1.00	7.45	23.45	1:3.15	32.
1.33	8.45	24.45	1:2.89	37.
1.67	9.45	25.45	1:2.69	42.
2.00	10.45	26.45	1:2.53	45.

From this table we find that the variation is decreased from 1:3.94 when batteries having internal resistance of .33 ohms are used to a ratio of 1:2.53, when batteries of 2 ohms internal resistance are used.

These tables likewise show why it is that even a slightly defective joint in the primary circuit prevents the action of the transmitter.

Polarization is a defect of even more importance than internal resistance. It is not uncommon for a Leclanché battery to decrease 30 per cent. in E. M. F. after ten minutes' use. This of course decreases the average current in the primary circuit of the transmitter in a like ratio.

Having noticed now the importance of low and constant internal resistance and constant E. M. F., I will next call attention to some of the causes which operate to render telephone batteries not only poor to start with but unreliable in service. Lack of porosity in the porous cups is frequently the cause of high battery resistance.

Commonly, porous cups are found which contain peroxide of manganese dust. This dust should never be admitted, as it invariably increases internal resistance. The peroxide should be in particles about the size of small peas. Binding posts are frequently found which do not make good connections with the electrodes. The binding post on the carbon plate is often found after a few months' use to be almost entirely insulated from the plate. This is caused by the salts creeping up through the carbon, and corroding the metal binding post. The upper portion of the carbon is supposed to be entirely impregnated with paraffine to prevent this crawling, but very often the carbon is not soaked long enough to become thoroughly saturated. Care must be taken not to use an excess of sal-ammoniac in setting the battery up, for otherwise crystals will form on the zinc, increasing very much the internal resistance. If the sal-ammoniac becomes impoverished a complicated chloride of zinc will deposit in the same manner. A poor quality of the peroxide of manganese is frequently found in porous cups. When such is used polarization takes place very quickly.

Gravity batteries and bichromate of potash batteries have been used to a considerable extent, especially for long-distance transmitters. These batteries require much more attention than the Leclanché battery, and are not so reliable. The battery, which, in its electrical properties, approaches more nearly the ideal battery, is the storage battery. This combines constant E. M. F. with very low internal resistance. Two cells of storage battery on a long-distance transmitter give the very best transmission. This form of battery cannot, of course, be generally used on subscribers' instruments.

Many modifications of the Leclanché battery have recently been introduced, some having remarkably low resistance; but they all polarize more quickly than is desirable. I think that if we have not already a modified Leclanché battery that combines low resistance with constant E. M. F., that we will soon have one, and this will be beyond question the telephone battery of the future. I see no reason why a battery of this kind could not be made having an internal resistance of considerably less than .5 ohm and a constant E. M. F. of 148 volts. This battery could be put up in a package with nothing but the terminals projecting, and these I may say should be provided with the best possible forms of binding posts. By using nothing but the best material, and properly designing the electrodes, polarization could to a very great extent be prevented, and by properly proportioning the components exhaustion would take place in all the parts about the same time. Such a battery would give, when set up,

the very best possible results and would require no inspection. When the battery became exhausted no unsatisfactory doctoring would be done by the inspector; he would simply replace a battery by a new one. Until some such battery is generally introduced we may expect about the same percentage of battery troubles that we are now having.

DYNAMO CURRENT INTERFERENCES WITH TELEPHONE SYSTEMS, AND MEANS OF RELIEF.

BY C. L. MC CLEUR.

DURING my earlier telegraphic experience I became imbued with the universally accepted belief in the theory that the earth was an immense reservoir of electricity, and that on that account, and because of its immense mass, it offered no appreciable resistance to the transmission of electrical force. Hence the universal use of the earth as a return conductor for telegraph and other electrical circuits, which are in consequence called "mixed circuits," in contradistinction to circuits composed wholly of metallic conductors. But my attention being called to the behavior of our telegraph apparatus under the influence of extraneous currents, I was finally led to question the correctness of the theory of the "infinite conductivity" of the earth.

Like nearly all of the early workers in the new field opened up by Professor A. Graham Bell's invention, I was also led into the error of attributing to "induction" nearly all the ills to which the telephone was heir.

Experience and observation, however, soon convinced me that nearly all the telephone troubles popularly supposed to arise from "induction" were the result of "leakage" only; induction operating only at minute distances, while leakage would occur across wide intervals. Hence I was to some extent prepared for my subsequent experiences with the effects of electric light and electric power circuits upon telephone systems, experiences which, as I will now proceed to explain, confirmed me in my disbelief in the theory of "infinite conductivity" and the effects of "dynamic induction."

Some three or four years ago, Richmond was captured by the advance guard of the army of Knights of the Dynamo, to which she is now so largely tributary, and the Schuyler Electric Light Company soon had the city ablaze with arc lights. At first we experienced little or no trouble, but after a time strange noises were heard in our exchange telephones, and as the electric light construction was extended and circuits and arc lights were multiplied, the noises increased until they finally became a din, over which it was almost impossible to project the voice. After careful consideration, I suggested certain reversals of dynamo currents, and re-arrangement of the electric light metallic circuits, which were adopted by our electric light friends, greatly to our relief. But on some of our exchange wires, notably those on our Broad street trunk line extending to the extreme western and northwestern limits of the city, the howling of the dynamo currents remained comparatively unabated. After further consideration I became convinced that the principal source of our telephone troubles was a long electric light circuit, which traversed Main street to the western limits of the city, then crossed north ward to Broad street, which it followed eastwardly to a point opposite the power house, and thence in a southerly direction to the dynamo, thus making a loop about a mile and a half in length by a quarter mile in width. One side of this loop ran parallel with our Broad street trunk line, almost the entire length, with only the width of the street between them. I was at first inclined to attribute to the usual scapegoat "induction" the interference which we experienced on our Broad street wires, but my attention being about this time directed by some of my linemen to the interesting fact which they had discovered, that even in the dryest weather enough of the dynamo current on this large loop escaped over the insulators and down the poles, to be perceptible to the tongue when applied to a pole four or five feet from the ground, while in rainy weather a very perceptible shock could be felt by applying the hand to a wet pole.

My former opinion regarding "induction" versus "leakage" and the "infinite conductivity" of the earth were recalled to me with redoubled force, and I soon settled down to the conviction that *leakage* was the force with which I had to deal. This conviction was strengthened by the well-observed fact that the interferences from the electric light currents were greatly increased during wet weather.

But the famous Richmond Union Passenger Railway, with its street cars propelled by electricity, became a moving, flashing reality in January of the present year, and for a time rendered the telephone business in Richmond decidedly interesting. Unlike the electric light and power systems, the electrical plant of the railway company was not designed or arranged for metallic circuits, but was, and still is, operated by mixed earth and metallic circuits, the currents being carried to the overhead trolley wires by a system of distributing mains, supported upon poles on one side of the street, these mains being connected at frequent intervals with the trolley wire by short lateral wires termed "feeders." As operated in Richmond, the electric railway system requires a double line of poles, one line on each side of the street for the purpose of carrying short non-electric wires, which extend across the street between each pair of poles. These are termed "supporting wires," and are designed solely to support the trolley wires at the proper height above the middle of each roadway. These supporting wires and the network of special supporting or curve wires, whose office it is to cause the trolley wires to curve parallel with the curves in the road-bed, are supposed to be insulated from the trolley and feed wires and mains; but, as we found to our cost, they were not by any means devoid of electrical currents. During the first six weeks after the inauguration of the electric road we had eight sets of telephones and one central office annunciator drop burned out by the railway currents, and about half of these accidents were due to crosses between our telephone wires and the supposed-to-be-harmless supporting wires. While these accidents demoralized our linemen and operators to some extent, they fortunately resulted in but little damage to property and none whatever to human life; and but few of our subscribers learning of them, they created no special commotion.

But the effect of the railway system upon our central office apparatus and telephones, from the very inauguration of the railway plant to the present time, has been annoying in the extreme, and exceedingly detrimental to our exchange service. Almost the first revolution of the battery of railway dynamos tripped the annunciators of our magneto lines, and rendered necessary an immediate resort to the use of special armature springs to overcome the magnetism imparted by the currents from the railway wires. Our "testing-off" galvanometers were rendered inoperative, because at first the polarity of the extraneous currents was opposed to that from our galvanometer batteries, and the galvanometer needles were deflected in a direction contrary to the position assumed when under the influence of the batteries alone; the leakage from the railway wires being sufficiently strong to overcome the current from three cells of Law or Leclanché battery.

This trouble I remedied by reversing the poles of my galvanometer batteries so they would, with the exception to be mentioned, coincide in polarity with the extraneous railway currents. And this exception, coupled with the continuous and steady nature of the extraneous currents, confirmed me in my belief that it was leakage and not induction from which we were suffering.

At the power house or dynamo rooms of the railway company, distant three or four squares from our central office, the battery of five or six dynamos which furnished the current for the car propulsion, was grounded, the negative electrodes being connected to several large sheets of copper at the bottom of a deep well upon the premises, the positive electrodes of the dynamos (coupled up, of course, in multiple arc) being connected "to air," as a telegrapher would put it, or to the distributing mains. From all of our exchange stations located in the vicinity of the dynamo rooms, within the radius of an entire block in fact, we would therefore get a negative leakage current, while from all other stations which were grounded within a square of the railway track and wires, we would obtain a positive current, thus rendering it impossible to arrange our galvanometer batteries to coincide with these leakage currents of opposite polarity.

We cannot, therefore, to-day use our galvanometers for "testing-off" the few stations located in the immediate vicinity of the dynamo rooms. Identically the same effect was produced upon our head-phone test circuits, the railway currents completely neutralizing the currents from our "test" batteries. This difficulty was also remedied by reversing the poles of the batteries.

The exchange lines most greatly affected by the railway currents we found by experience were those which were grounded nearest to the railway tracks, irrespective of the general direction of the wires or their proximity to or distance from the railway; lines that in no place approached within less than a square of the railway wires being as greatly affected as many others that ran parallel with, and in close proximity to the railway wires for long distances, but which terminated and were consequently grounded at points comparatively remote from the railway.

In like manner, lines grounded near the heavier grades and curves of the railway, where the motor men are compelled to use the maximum amount of power in order to ascend the grades or round the curves with heavily loaded cars, are more seriously affected than lines grounded near the levels. So clearly is this the case that our operators can readily tell from the character of the disturbance which they experience, when a car is ascending a grade, or when it stops or starts.

This effect of the movement of the cars you, of course, understand is due to the fact that the dynamo currents, when propelling the cars, are short-circuited from the trolley wires through the motor fields and armatures to the earth, thence spreading over every available conductor in their efforts to reach the dynamos. But the maximum disturbance is experienced when three or four cars are following each other in close file, either on a grade or level. In that case the leakage due to each car traverses the contiguous telephone wires simultaneously, producing in our telephones a composite or mixed tone, each motor having its distinctive "timbre" or tone quality, and all united fairly

making Rome—or the telephone, rather—howl, and drowning out the puny currents induced by our microphone batteries.

Learning that the railway people were utilizing the municipal gas and water mains in order to reinforce their ground connections, it occurred to me that possibly the fact of our lines being generally grounded on the gas and water pipes had much to do with our troubles. I had some of our wires removed from these systems and connected direct to the earth through made grounds, but without altering the results.

The 450 or 500 volt currents of the railway mixed circuit system do not, however, interfere as greatly with our Richmond exchange service as the 4,000 or 5,000 volt currents carried by the metallic circuits of the electric lighting systems. Did the railway service require currents of the same E. M. F. as the arc lights, the telephone would have to retire from the field—lose ground in fact—as metallic circuits would be their only salvation. What the railway currents lack in E. M. F., however, they make up in current strength, and are, therefore, more dangerous to property than the much more intense electric light currents. The latter will melt a fuse or burn out an arrester instantaneously before time is given it to enter a central office or a subscriber's station, and damage the telephone or outfit; while the less rapid but larger quantity of the railway current takes an appreciable time to melt or fuse an arrester, thus permitting it to burn out a hand-phone, an induction coil, or a bell or annunciator magnet, before the protector, of whatever kind it may be, can properly act.

In my experience the greater tension of the electric light currents renders them doubly disastrous to telephone exchange service, the voice being more completely drowned by the intense disturbance due to the electric light escape than it is by the escaping currents from the lower tension dynamos. But the fact of the electric light being in demand, particularly the arc lights, only after business hours, renders the disturbances engendered by them less noticed by subscribers generally than the weaker and less marked disturbances proceeding from the railway generators, which are continuous throughout the entire business hours of the day, when the telephone service is in constant demand. Did the arc light service continue during the hours of daylight as at night, telephone exchanges would be compelled to suspend operations or adopt the only alternative, metallic circuits, with the attendant increase in complication and expense.

Having thus discussed the effects of extraneous electric light and railway currents, let us address ourselves to a brief consideration of the remedies which we have at hand. Anti-induction devices for the elimination or exclusion of extraneous currents from telephone circuits, whether they be artificial or natural, are plentiful, but none have yet been devised that can at all compete with the old style metallic circuit.

But the metallic telephone exchange system carries with it not only a double expense for construction, maintenance and repairs, but a vast outlay and increased complication and expense for central office plant and service, there being two line wire terminals to provide for every subscriber, and necessarily four terminals to handle for every connection, instead of two, as with the single wire and earth systems.

This great increase in wires, in complication and consequent liability to derangement, and in initial cost, and subsequent expenses for operation and maintenance, almost prohibits the adoption of the ordinary metallic system. None but the wealthy, like our long-distance friends, can afford such a luxury. But there is a metallic circuit system within reach of even the poorest of the American Bell Telephone Company's lessees, a system of my own devising, and which I have found by practical tests to accomplish all that can be desired from an ordinary metallic circuit, and at but a tithe of the expense.

Recurring now to my theory that it was not "induction," but leakage, that annoyed us, and the expression of my disbelief in the infinite conductivity of the earth, it will readily be seen how, after arriving at those conclusions, I would very naturally reason thus: If our telephone troubles are due to leakage from the electric light and railways, and this leakage overflows into our wires from the earth *because* the earth offers an appreciable resistance to their passage, why cannot we adopt a metallic conductor of exceedingly low resistance, or of a conductivity approximating that of the earth, and use *it* in place of the earth as our return conductor, making it, in fact, what may be called an "artificial" earth or ground, and at the same time cutting loose from the earth entirely and gaining all the benefits of metallic circuits?

This idea I conceive to be in strict conformity with Ohm's law; and if only the relative resistance of the "artificial ground" or earth, and the line wires attached to it, were properly adjusted, we would have identically the same results achieved by the usual earth connections, and without the disadvantage of the mixed circuits. This thought revolved in my mind for some months before I could find time and opportunity to verify its truth or falsity by experiment. Besides, the device was so simple that I could scarcely conceive that it was possible that it had not already been tried and found to be impracticable by some member of the army of electricians that had been so long engaged in efforts to solve the anti-induction problem; and it was only after conferring with some of my brother telephonists, who were favorably impressed with the idea, which was novel to them, that I took the time necessary for experiment. I, however, finally connected up several telephone circuits with a common return wire of low resistance, and found that conversations could be carried on, and a magneto call-bell rung on each circuit without any mutual interference whatever, and it required a resistance of 35 ohms by galvanometer measurement to be added to the common return wire before the currents propagated in one circuit could be heard in the telephones on the other circuits. I thus concluded that there was approximately 350 ohms resistance in each circuit, due to the conducting wire, the call-bell magnets and the hand-phones and transmitters, and that the "artificial ground" wire should bear to the other side of each circuit, the direct or line wire, a resistance approximating one-tenth that of the entire circuit.

Encouraged by this experiment and anxious to do something to improve the night service of my exchange, I laid my scheme before the executive officers of my company, and was furnished with a half mile of No. 4 copper wire with which to make some practical tests. My first experiment was with our No. 19 northern call wire and its connecting lines. This was our shortest call wire, being only a third of a mile in length, and had connected with it some 18 or 20 subscribers' stations, located in close proximity to the Seventh street grade of the electric railway, an 8 or 10 per cent. grade, extending from Franklin to Grace street, one square. At the corner of Seventh and Franklin streets, the main feeder wires of the railway plant direct from the power house, two squares distant, first touched the line of the railway and divided right and left to the opposite and distant ends of the road. At this point, as might have been anticipated, on our telephone lines grounded in this vicinity we experienced the greatest interference, particularly when a heavily loaded car was ascending the hill. My "artificial ground" gave us immediate and remarkable relief from the railway leakage, and without any cross-talk whatever. I then applied a half mile of No. 6 covered copper wire, which I connected to the end of the first half mile of No. 4 wire, and extended the artificial ground wire on out to the western end of the city, intending to make my next test with one of our longest taps and our longest lines, with stations located near the most westerly extension of the long Main and Broad street electric light loop, of which I have already spoken. These lines had been almost entirely abandoned at night, our subscribers averring that they could not use their telephones at all after the electric lights were ablaze.

The worst of all was a station in a drug store, whose proprietor had long made bitter complaint that his telephones were of no service to him after dark. Yet when the change was made from the natural to the artificial ground, at this and all other stations on that call-wire tap, the relief from the electric light leakage was as instantaneous and marked as that experienced from the railway leakage on short tap No. 19. In fact such was the change wrought on these wires that it was possible to carry on a whispered conversation over lines connected to my artificial ground, that when connected to the natural earth were so noisy that even the loudest shouting could be heard only with extreme difficulty.

While cogitating over my idea in its incipiency it occurred to me that even the adoption of a *general ground wire* of high conductivity would relieve our telephone wires from the influence of these extraneous currents to a great extent. This I found from experience to be true.

When arranging for the central office end of my "artificial ground," I had made a plug switch so arranged that by the insertion or removal of a single plug I could connect the artificial ground wire to earth, or disconnect it entirely from the earth, and with one motion connect it with all of its attached wires into a "compound metallic circuit system." I could thus readily note the difference made by the use of the large copper wire as a *general ground wire*, or as a substitute for the earth. In the one case, as you understand, if I have made the matter clear to you, the large copper wire was connected to earth at only one point through the plug switch in the central office, while in the other it was disconnected from the earth entirely.

To those familiar with the details of a telephone exchange, it will be clear that some such provision for grounding or connecting artificial grounds to earth is essential, as long as any of the wires of the system remain in connection therewith, because of the necessity of connecting stations not yet changed to the artificial ground to those that have been thus changed; otherwise the one will be grounded and the other "dead open," and, consequently, inoperative. In this way I found by experiment that, when the large copper conductor was to earth at the central office and was being used simply as a general ground wire, the electric light and street railway interferences were reduced about 50 per cent., and when used wholly detached from, and wholly in place of, the earth, they were reduced the other 50 per cent., or eliminated entirely.

By thus utilizing the large conductor, *first*, as a general ground wire to carry the microphone and signaling currents to the earth at the central office, or at any other locality remote from the offending electric light or railway plant, an exchange

system can be gradually converted from a mixed metal and earth system into a compound metallic circuit system throughout, without any interference whatever with the service of the exchange, and to its manifest improvement during the time the change is being made. And when the last subscriber's line has been transferred from the natural to the artificial earth at the last station, it is only necessary to withdraw the solitary plug that still connects the system to the earth, and, presto! you have an exchange of purely and practically metallic circuits alone, with all of the advantages of the ordinary metallic circuit systems, the one series of large copper wires extending out on the various trunk lines, but all united in one at the central office, answering fully the purposes gained by the ordinary duplication of each individual wire, and necessitating no change whatever in either central office or station outfits or appliances, beyond the simple substitution of the artificial for the natural ground.

In practice it may be found that a greater proportion than one-tenth the resistance of any one circuit may safely be given to the artificial ground wire, but my experience and experiments lead me to believe that it will be far safer and more satisfactory to keep the resistance of the artificial ground to one-twentieth that of the entire circuit.

In an exchange the size of our Richmond exchange, I advocate the use for each individual trunk route of a single copper conductor, composed of a half mile each of No. 4 and No. 6 wire with No. 8 for lateral lines and the remaining distance to the farthest stations, with No. 14 to stretch from the poles into the stations. All of these wires should be of hard drawn copper with a good covering, and strung on the same poles and fixtures that carry the regular exchange wires, but insulated carefully both from them and the earth. And I should place these artificial ground wires at the lowest point on the poles, or the least distance from the sidewalk or ground, beneath all of the line wires if possible.

In this position the small amount of leakage currents that are attracted up the poles from the earth, whether from electric light, electric railway and power circuits, or earth currents, will be intercepted by the large copper wires, and by them carried to those points in the system where they will escape to earth again without any adverse influence upon telephone wires proper.

While in the absence of any direct experiments I cannot say positively that such will be the case; I believe, however, that if our long-distance friends will couple together so as to make of some eight or ten of their No. 12 or 14 copper wires practically a single low resistance conductor, they will find that this compound conductor will answer as an artificial earth or return wire for treble or quadruple the number of wires thus coupled together, while a single conductor of the same conductivity would double the capacity of their poles and the number of their metallic circuits. In like manner, I believe the same principle can be applied to telegraph and electric light or power circuits, relieving them from the disturbing and damaging influences of earth currents and atmospheric electricity, and conferring upon them all the advantages of metallic circuits without the ordinary duplication of wires.

In conclusion, allow me to say that, while I flatter myself that I am charitably disposed and ever inclined to do all that within me lies to further the interests of the telephonic fraternity and increase the efficiency and value of our telephone service, I do not think I am justified in assuming the role of public benefactor and giving my device away, even in the interests of science. Believing it to be novel, practicable and valuable, I have therefore conceived it to be my duty as well as privilege to apply for a patent, and my application is now pending, with, I trust, a good chance for a favorable decision.

ON THE ELECTRICAL RELATIONS OF TELEPHONE AND ELECTRIC LIGHT AND POWER CIRCUITS AND RAILWAYS.

BY T. D. LOCKWOOD.

THIS paper deals altogether with the disturbing effects of electric light and power currents upon telephone lines, and not at all with the dangers of imperfect construction and insulation; nor with the results and prevention of dynamo current crosses, there being sufficient in the latter branches of the subject for a separate and equally voluminous paper. It will consequently be assumed for the purposes of this paper that the important precaution of effectively insulating wires conducting heavy currents is observed, and that "undertaker's wire" is, as it ought to be, a thing of the past.

The telephone exchange business was commercially organized and established in the first months of 1878. Electric lighting as a commercial industry had its beginnings in 1878 and 1879, but did not at first take root with the same degree of rapidity which characterized the exploitation of the telephone, and not until some years thereafter did it achieve popularity.

Consequently the telephone systems obtained considerable start, and were firmly established in nearly every city and town in the country before the organization of many electric lighting systems. It was not at the outset generally known that the telephone circuits would be annoyed by the presence and proximity of parallel electric light wires; and telephone companies were thus at first most liberal in permitting the erection near their lines of foreign lines carrying heavy and widely fluctuating currents. Yet, a little thought and consideration would have laid bare this danger. We knew that the telephone current was itself of most shadowy and almost intangible character in point of strength, and that to utilize it such a super-sensitive instrument as we all know the telephone to be was actually essential. And we knew that *because* the telephone receiver was such a delicate electroscope, and so sensitive to electric motion, we had heretofore been much annoyed by mutual telephone induction, by telegraphic induction, and by miscellaneous induction. So, as I say, if we had carefully considered the matter, we might have foreseen the full extent of the electric light disturbance which is now being sustained.

But we did not foresee, and as a result of our lack of foresight indiscriminate construction has ensued; and in consequence of improper construction the business of many telephone companies has, at certain points, been directly or indirectly injured by the presence and operation of electric light wires, and an appeal to the courts has been rendered necessary.

Until within a comparatively recent period the disturbance resulting from dynamo current induction was, with an occasional and rare exception, limited to certain evening hours, and to the night, because during such portions only of the day were the lighting circuits in operation. But of late, in many places, the wires used in the night for lighting are also used during the hours of daylight for transmitting power from the dynamo to large numbers of motors which may be widely distributed; and as this utilization is certain to have in the near future an enormous expansion, we are compelled to face the prospect that even during the hours of business, telephone wires are now liable to severe disturbances. Therefore, it seems time to call a halt; we could be patient so long as we were only called upon to suffer from the "pestilence that walketh in darkness," but when we are also threatened with the "destruction that wasteth at noonday," it behooves us to have something to say about it. Super-added to the above causes, we now find that electric railways are being introduced in rapid succession, and we find to our cost that many of them are much more active than are electric lighting circuits in setting up disturbing currents in telephone lines; the disturbing current from electric railways being frequently sufficiently strong to vitalize the annunciator magnets of a telephone central station, and to actuate the drops.

Now, I have no quarrel with electric light and electric railway companies, considered as such. No man rejoices more heartily than I in the triumphs of electricity and in the tremendous spread of its usefulness. I recognize fully, moreover, that the lighting, power and transit utilizations of this mighty form of energy are fully as useful as is its function in carrying intelligence; and that these utilizations have properly become permanent institutions, and, equally with our own, public conveniences. Nevertheless we were first in the field, and although we may admire both the energy of the electric lighting current and the energy of its introducers, we must in our own defense be prepared to take the position that no newcomer has a right to construct his plant in such a way that an established business shall thereby be ruined or impaired, and that if it be absolutely necessary to erect electric light lines in close proximity to telephone lines, the construction must be of such a character as not to involve detriment to the pre-existing telephone lines.

Can electric light and power lines be constructed so as to be near telephone lines without interfering with them? Certainly they can. Consider how the disturbing currents originate: First, most arc lighting circuits can set up considerable induction on telephone lines. Second, alternating currents in main wires, whether used for arc or incandescent lighting, are intensely provocative of induction and noise in telephone circuits, the character of the disturbance being much worse than that which is produced by lighting currents of constant direction, this latter sounding in the telephones like a protracted musical note of great volume. In speaking of the above it will be understood that the detrimental action upon telephones is the same when the dynamo current is used for motors as it is when used for lighting. Third, certain classes of electric railways very seriously interfere with the operation of telephone lines, both in conversation and also by establishing thereon a current which permanently excites the annunciator magnets. The noises which are produced in telephones by dynamo current induction are so well known that it would be waste of time to describe them.

When the troublesome currents are produced by electric light or motor circuits they may usually be attributed to induction; although a certain amount of absolute leakage, doubtless, also exists. Since, however, both causes produce in telephone circuits a like effect, it will be sufficient to speak of induction only. But if we consider the action of electric railways upon telephone lines, we find that the major part of the disturbance is due to the actual transference of a portion of the electricity which actuates

the train motor to the telephone lines, by way of the rails (when these are used as return conductors), the crust of the earth itself, and the telephone line terminal ground wires.

As most of us know, the alternating current has received lately an increasing amount of the patronage of our light-producing friends; and at the present time both constant direction and alternating currents are largely used in electric lighting and power distribution circuits, the intensity of the disturbance varying with the class of current employed.

The violence of the induction, and therefore of the disturbance, depends upon the proximity and longitudinal distance of parallelism of the disturbing wire, the strength of the inducing current, the frequency or rate of change per time unit of the inducing currents, and the extent or range of such change. That which is due to wires carrying alternating currents is, of course, much stronger than even the worst case of direct current induction, for even though the distance of exposure and the strength of the inducing currents be identical, it is self-evident that a current which is completely reversed a great number of times per second, must be much more energetic as a disturber of the peace than one which is constant in direction, and which varies only in strength on one side of the zero line. These considerations indicate that our methods of prevention or cure should be directed at the stronger disturbing agency, since such a degree of success as we may be able to achieve against that will necessarily be equally effective as regards the weaker.

The proper way to cure or neutralize electric light or power induction *is to prevent it*. It is quite within the bounds of good construction so to relatively arrange lighting and telephone circuits that no disturbance will result; and it is obviously much easier and less costly to construct them properly in the first place than it is to change them. To secure this most desirable result, viz., the harmonious co-existence of these widely differing classes of electric service, I wish to point out that co-operation between the parties concerned is absolutely essential, together with a clear and full understanding of the conditions involved. Yet in too many instances, though, as I have stated, where the telephone wires were already in the occupancy of the field, telephone companies have negligently omitted to watch their own interests with sufficient care, and have, without remonstrance, permitted electric light companies to erect wires close to their own, and of such a character as to render inductive disturbance a foregone conclusion. Would not a general good understanding between the different electrical interests of any city or town be desirable for the forestalling of such chances of future disagreement? Informal discussion, amicable conference and mutual consideration between the authorities of the several interests would tend to preclude any possible future misunderstanding, and would certainly act to prevent unnecessary antagonisms either between any of the several individual interests or with municipal authorities. A good understanding all round is therefore suggested, as being an admirable forerunner to a system of non-conflicting construction.

Local managers of telephone companies should be instructed to report to headquarters at once, the intended construction of either electric light or railway circuits at any point within their territory, so that proper measures can be concerted, and adopted to meet the special conditions of the case. If the general satisfactory understanding, which I have outlined, can be reached, it should not, I conceive, be difficult to bring intending electric light and railway officials to see that construction which is innocuous to their neighbors, and which, in virtue of the provisions necessary to secure such innocuousness is thereby made safe in all respects, is (all things considered) both cheaper and better than construction which is at any time liable to involve them in trouble, misunderstanding and damages.

The element of distance is of the highest importance. Telephone and electric light wires cannot be too far separated for the efficient working of the former; and the wires last strung should be run, if possible, on the other streets from those in which wires are already in operation. In no case ought the two classes of circuits be nearer together than the width of an average street. In writing the above, I have not forgotten that it is oftentimes a matter of mutual convenience, that reciprocal privileges should be allowed. This idea is by no means in conflict with the general principle that distance is the most efficient neutralizer.

The good feeling and understanding which I have advocated will be productive of a tendency to keep down unnecessary pole construction, and if either interest have a pole line through a certain territory, and if the other party have but a few wires going in that direction, it is doubtless often the best policy and practice to make the existing pole line available for both. By suitable agreement on this head, both telephone and electric light systems are enabled to use each other's poles on occasion, and thus to carry a sporadic line, and accommodate a customer in districts which could not otherwise be reached, at least with due regard to economy. It is, of course, understood that an electric light company thus stringing wires on the poles of a telephone company must properly run its wires so as to produce at most a minimum disturbance, and that a telephone company taking its chance on electric light poles must not expect first-class results, unless it be returned through the region of disturbance. The responsibility in the latter case is on the owner of the telephone wire alone.

If both sides of the street be fully occupied, and it should be really necessary to carry a main route of wires of both systems on the same side of any street, no other street being available (a state of affairs which ought not often to exist), it would, I should say, be better for them to be upon a single line of large poles than for each company to provide its own poles, and thus to incur the enmity of abutters, property holders, municipal authorities and iconoclasts generally, for a uniform style of construction can then be adopted; and as the telephone current is the weaker, the telephone poles should carry both sets of wires, and the construction should be supervised by its officials. This procedure is, however, only admissible if no other route can be found for the wires of that concern arriving last on the ground; and I repeat that wherever circumstances will permit, the width of an ordinary street at least should intervene between the wires of the two systems.

Electric light and power circuits ought always to be metallic, and in fact every self-respecting electric light circuit *is* metallic; this, however, being altogether without regard to its relations with contiguous circuits of other classes. But a lighting or power circuit which is contiguous to telephone circuits must not only respect itself, but must respect the telephone circuits also, and hence must not only be a metallic circuit, but must have its two wires parallel and as close together as possible, so as to be practically equidistant from the telephone wires; this, in order that the inductive effect exercised by the outgoing and incoming wires may be equal and opposite.

Where the distance of the width of the street is observed the parallel return wire frequently provides all the necessary neutralization, and prevents disturbances, for the neutralization is necessarily more perfectly effected as the distance of the two wires of the electric light circuit from the telephone wires is increased, because the distance of the two wires of the lighting circuit from one another is a much less factor in a greater distance, such as the width of a street, and the two wires therefore operate much less independently than is the case when each wire is almost as near to a group of telephone wires as it is to its own mate. It is, however, often found (and especially when the two sets of wires are on different horizontal planes of the same poles) that even though the two wires of the lighting circuit be substantially equidistant from the telephone wires, perfect neutrality and noiselessness is not secured; and the degree of remaining disturbance is greater or less according to the distance between the wires of the two systems and the distance that the said two sets run in parallel contiguity. This remaining disturbance manifests itself because the electric light circuit is not balanced. If, for example, one of the two sides of a lighting circuit be made to serve one or more lateral loops, while the other runs straight, or if one be connected with a greater number of lamps than the other, there is no balance; the electrical centre of the main line does not coincide with the mechanical centre, and one of the two wires exercises a much greater inductive influence than the other, the result being noise. By arranging the electric light circuit so that each side shall have an equal number of loops of like length, and an equal number of lamps or motors, and then by transposing or crossing the two wires of the lighting circuit about every fourth or fifth pole the disturbance may be totally suppressed.

Such care in construction will most naturally be objected to by electric light and similar companies on the plea of expense, especially by such as have already constructed their lines in a style regardless of the rights of others; yet only by an insistance upon such conditions, when the two systems of lines are in close proximity, can the business of telephone companies be protected.

It may also be objected that since the parallel return wire cross connected at intervals with the outgoing wire is a remedy for inductive disturbances, it is one which should be applied by the telephone companies, and to the telephone circuits, as being the complaining party. But as to this, in addition to the already stated fact, that in nearly every case where the pernicious effects of induction are experienced, the telephone company was already in business and its wires in place, and that the disturbance originated with the advent of the electric light wires, and that common justice requires that the aggressor should apply the remedy, it may with reason be rejoined that the number of the electric light wires is much less than that of the disturbed telephone wires, and, therefore, the remedy may be applied to the former with much greater ease and at much less expense.

We have considered the preventive or remedial measures which are applicable to this evil; and it seems clear that the right time for suggesting the propriety of observing these conditions of neutral construction, is before the work has been done, and it is probable that the owners of disturbing wires will be much more willing to heed them, in originally arranging their wires, than where subsequent alteration is required; especially as in original construction, the plans suggested would not necessitate the numerous joints inseparable from later transpositions.

In any case, whether such remonstrance or suggestions as may be offered, tending to harmless construction be properly received and acted upon or not, it is our duty to offer them, and so to place

ourselves in the right, and in this unmistakable position of having, at least, done our part in objecting to improper, and in stating our convictions of what constitutes proper construction.

I have already alluded to electric railways, and to the fact that the weight of the evidence in regard to disturbances developed by them upon telephone lines tends to show that these are due not to induction, but to actual leakage of electricity from the railway conductors to the telephone lines.

There are several classes of electric railway: first, those which utilize the rails for both outgoing and return conductors. Second, those which employ a single overhead conductor, using the rails as a ground terminal or return. Third, those in which the two main conductors are both in a conduit, to which access is had through a slit in the same way as a mechanical cable road is operated, trailing brushes or springs being led through the slit. Fourth, railways which carry their own electrical energy in the form of secondary battery cells. Fifth, railways which employ two overhead conductors—one as the outgoing and the other as the incoming line.

Of these plans, the first and second are very detrimental to the satisfactory operation of telephone lines; the fourth is perfectly harmless in all respects; and the third and fifth usually are also, and may be readily so made when they are not. All that is necessary to that end is to exercise such care in construction as to insure that the main conductors are properly insulated, and in the case of the fifth plan, that the main conductors are also prevented from coming into contact with overhanging branches of trees.

A great number of electric railways are built upon the second plan, and where they are run near telephone wires invariably exert a pernicious influence thereon, which is largely due to the imperfect return or earth terminals furnished by the rails; a portion of the current passing from them through the earth to the telephone circuits by way of the sub-station ground wires, thus occasioning interference with conversation, and affecting call signal apparatus, and often damaging property.

This class of construction is manifestly improper, both on the score of interference with the telephone wires and as being dangerous, and is of the cheap and reckless order.

When the remedies for its evils are so simple, and consist merely in adding a second overhead conductor, and in looking well after insulation, it would seem that they should be properly and universally applied by reason of the greater security they afford, even though those owning railways may have no just regards for the rights of others.

Telephone companies should, therefore, exert themselves and their influence in favor of the double overhead wire and other safe forms of railway, the former being, in fact, safer in other respects and more economical in operation than railways, which in any way utilize the rails as conductors.

When other systems are already in use, and should it be found impossible or impracticable to persuade the railway company to provide a return wire, and where the telephone service is consequently impaired, the only absolute remedy is that of providing the telephone circuits which are affected, with a parallel return wire.

The disturbances may, however, be greatly softened down or subdued by carrying the ground end of the subscriber's wire from his office or house to some point at a considerable distance at one side or the other of the railway, and by their terminating it instead of at the sub-station itself. Considerable success has also been attained in practice in the amelioration of this trouble by connecting the leading outwires of a number of neighboring disturbed telephone lines with a large common return wire grounded at or near the central station, instead of grounding each in the ordinary way.

If the leak is so great as to affect the annunciators, it is sometimes requisite that the common return wire, instead of being grounded, shall be connected with the several central office terminals of its group of lines, exactly in the same way that its outer end is united to the outer ends of the individual lines; that is, of course, when these are at rest. By adopting this plan the earth connection is, when the lines are not in operation, completely cut off. If the disturbance does not affect the talking, ground connections can be provided for use during talking. If it does, then the return must be retained during talking also.

Though this paper is already long, there are still one or two points on which I should touch. In one of the children's hymns composed by the late lamented Dr. Watts, occur these lines:

> "One sickly sheep affects the flock,
> And poisons all the rest."

And upon the principle thus enunciated, it not infrequently happens that, though but few telephone wires, or even a single wire, be exposed to disturbance originating in and by the causes recited, the trouble is propogated to others by induction, by reason of the close massing of a large number of wires at or in the vicinity of central stations.

Consequently, one wire adversely affected by electric light or railway disturbance may influence deleteriously many others. The lessons we have to learn from this are, that if we have one wire so affected, we ought, in some way, to promptly attack the evil in that wire, remedying the trouble while it is small and controllable; and that it is essentially our duty to remove dead or unused wires at once, unless there is good reason to anticipate an early resumption of use; and even then they should be disconnected from the two terminal stations; and when I say disconnected, I don't mean simply short circuited, or cut out, but absolutely detached, dead wire being one of the most prolific and active agencies of disturbance and danger. True, it costs something to take down wire, and it may be troublesome to put them up again when required, but it is the only safe proceeding, and in such matters the anchor ought to be cast windward every time. It is better to spend a few cents in defense than it is to spend possible millions on account of the misdoings of a dead wire in tribute.

Finally, if the number of disturbed wires be smaller than that of those causing the disturbance, or if it be necessary to run a telephone wire through a region of disturbance, the simplest, easiest and most economical way is not to monkey with the buzz saw, but at once to make the telephone circuit metallic, at least through the region of disturbance, which operation should, moreover, invariably be performed in cases where less drastic measures fail.

THE NEW YORK SUBWAYS.

BY L. F. BECKWITH.

In the following statement I have recorded a few data relating to the construction of electrical subways in the City of New York which may be of interest. The work was commenced in the latter part of 1886, and has been carried on since, with but slight interruption each year during the season favorable to out-of-door operations. The subways as laid out and built have been authorized and approved from time to time by the Board of Electrical Control, and the Consolidated Telegraph and Electrical Subway Co. has been directed by the board to construct them under its contract with the latter. The execution of the work has been intrusted by the above company to its sub-contractor, the Phœnix Construction Co., which has charge of all subway construction in this city.

The subways have been designed and laid out to meet the main requirements of the chief connecting or trunk lines of the various electrical companies so far as they could be ascertained, and so far as they could be conveniently grouped together. The principle of keeping the high tension electric currents for arc lighting and power in subways on one side of each street, and the low tension electric currents for telephone, telegraph, and other purposes in subways on the opposite side of the street, has been laid down and so far adhered to. The question of distribution from the conduits has been wisely left by the Board of Electrical Control to the various electrical companies to express their preference for the method best suited to their special systems. This the companies have been repeatedly invited to do, and while some have responded, and their methods of distribution having been approved as reasonable and feasible, they have been accommodated as rapidly as possible; other companies have held aloof and refrained from action, apparently wasting precious time and neglecting to occupy and secure their commercial field and districts.

The subways built, except the Edison, are all on the "drawing in" system, which provides a group of tubes or ducts extending from one man-hole to another, admitting of the drawing in and out of the electrical cables, and affording convenient access from the street. Different systems of grouping the ducts in the trench, and different materials have been employed, consideration being held of the importance of the line, the question of cost, the durability, tightness against water and gas, etc. Experience has shown us that a main conduit consisting of separate pipes which can be crowded or curved or kept apart is the best adapted to overcome the numerous obstructions met with underground, and frequently diminishes the trenching necessary. Screw-jointed, asphalted wrought-iron pipe laid preferably in hydraulic cement concrete present the greatest tightness of duct against gas and water, united with the greatest strength. The cement pipe and creosoted wood tubes present also features of great merit and adaptability. A special feature of New York subway difficulties is the steam heating underground system, of which the leaks in certain localities greatly interfere with the ducts and cables, precluding the use in such places of materials of construction softening or melting at about 160 to 200 degrees F. In the case of long telephone lines, the desirability of comparing non-metallic and metallic ducts in respect to their influence on low tension currents has also been kept in view. A continuous line of telephone and telegraph subway is now completed about seven miles long, and the above comparison can be made on five to six miles of this length.

The endeavor has been to provide a subway construction that will be most durable and that will give the best mechanical protection to the cables against injury from settlement of the ground, heat, water, gases, etc. The solution of the electrical question of underground working is one that relates to the man-

ufacture of suitably insulated cables, and belongs properly within the province of the electrical companies.

The work accomplished up to September, 1888, is shown in the accompanying table :—

Dorsett ducts, coal tar concrete	235,837	feet.
Zinc tubes laid in hydraulic cement concrete	68,883	"
Creosoted wood tubes	167,175	"
Cement pipe laid in hydraulic cement concrete	216,626	"
Iron pipe laid in asphaltic concrete	131,284	"
Iron pipe laid in hydraulic cement concrete	1,423,722	"
Iron distributing pipe	23,301	"
Edison iron tubes	222,794	"
Grand total length of single ducts	2,489,622	feet.
Grand total length of single ducts	472	miles.
Grand total length of trenches	37	"
Number of man-holes	523	
Total length of telephone and telegraph ducts	376	miles.
Total length of electric light ducts	96	"
Length of telephone and telegraph trenches	19½	"
Length of special electric light trenches	17½	"

Besides the above there is still about three-quarter of a million feet of single duct for telephone, telegraph and electric light purposes, authorized by the Board of Electrical Control to be built, that remains to be constructed, besides contemplated lines.

The standard size adopted for telephone ducts is 2½ inches clear inside diameter, corresponding to a capacity of 100 wires, or 50 conductors in metallic circuit grouped in a lead covered cable. The chief portion of electric light ducts other than Edison ducts are 3 inches clear inside diameter. The man-holes are all of brick laid in cement mortar with 8 to 12 inch walls and concrete bottoms. They vary greatly in form, and are from 8 × 12 ft. to 4 × 4 ft. 6 in. in size, and from 6 to 12 ft. deep. The street casting used has a double cover; the inner cover and rubber gasket are held down by a wrought-iron cross-bar, a bolt and padlock. The covers are practically tight against water.

The systems of distribution in use are as follows: For telegraph purposes, an iron pipe from a man-hole connects underground with a building or with the foot of a pole. For telephone purposes the above method is used, and also in connection therewith, a pipe running up the face of a building to the roof, where, from a fixture, the cable is divided for distribution on the block and surrounding blocks. Sometimes the pipe is carried up through an elevator or ventilating shaft. In addition to the above, in the down-town district, and along Broadway to Union square, an iron 3-inch pipe is laid in the trench above the subway, and provided at intervals of about 50 feet with malleable iron circular distributing or service boxes with screw covers 12 inches in diameter, with side outlets through which a cable can be conducted by a service-pipe into the buildings.

For electric light distribution the Edison company have their special system laid. The "Johnstone" cast-iron distributing conduit, with six ducts and flush boxes, has been authorized to be laid in Broadway, from 14th street to 35th street, for purposes of electric light distribution, and will provide all the necessary facilities for this district.

Up to August 27, 1888, there were 3,567 miles of wire laid in the subways by the Metropolitan Telephone & Telegraph Co. This company has laid a 100-wire lead-covered "Patterson" cable from Whitehall street to 58th street, a distance of about six miles. This cable is believed to be the longest of this size in existence underground. The Western Union company have about 100 miles of wire underground, and the Edison company about 126 miles. The Brush Electric Illuminating Co. are putting an 8-conductor "Standard" cable in the Broadway conduit from 14th street to 35th street, a distance of one mile, making eight miles of electric arc light wire. Other applications for space in the subways and for the construction of additional electric light lines are pending.

UNDERGROUND WORK IN BROOKLYN, N. Y.

BY W. D. SARGENT.

THE extension of underground conduits in Brooklyn has been restricted since my last observations on the subject to short sections, for the purpose of connecting our new buildings in the Brooklyn and Williamsburgh districts with the underground system. All of the new conduits have been made of creosoted wood, the ducts, 3 inches square, inside measure, with the exception of one short section of Macdonald creosoted wood, with round holes, 2½ inches in diameter. It is fully decided, however, that hereafter no ducts will be laid with an opening of less than 3 inches in the clear.

In order to make ample room for the conduits reaching to our principal office, No. 16 Smith street, we have built a tunnel the whole width of the street, high enough and wide enough to walk through, and it now carries 108 ducts with room for perhaps 60 or 100 more. There are special features in this tunnel and method of bringing the terminals of the cables into the building which it is difficult to describe or to reproduce in a drawing. The *Electrical Review*, of Aug. 4, 1888, gives illustrations which will convey some idea of the character of the work, and the members of the association are cordially invited to visit the office and inspect the arrangements for themselves.

The first sections of our creosoted wooden conduits have now been in service four years. There is no evidence of decay, and the ducts remain clean and dry, enabling us to draw in and withdraw the cables without any difficulty.

So far as the conduits are concerned, we think experience has fully sustained our judgment in favor of the creosoted wood.

One of the most important things, after the conduits, in underground work is the man-holes, which should be as large and commodious as possible. Within reasonable limits it is almost impossible to get these man-holes or working chambers too large. While, from the start, we realized the importance of this part of the work, we have in quite a number of instances, been compelled to rebuild and enlarge the man-holes as first designed. Given a conduit of durable material, connecting with commodious man-holes, this part of the underground problem, so far, presents no serious difficulty.

The character of the cables to be drawn into the ducts and the method of distributing wires from them are questions that demand our most earnest attention. Experience has taught us that larger conductors and thicker insulation, together with twisted metallic circuits, are an essential part of perfect service. Conductors of .035 to .040 of an inch in diameter, insulated to .125 of an inch in diameter, and twisted in pairs, with 100 to 104 wires, or 51 or 52 metallic circuits, make up a cable of from 2 to 2¼ inches in diameter. Such a cable will weigh between 4 and 4½ pounds per foot, according to the amount of lead; and on account of the tendency of the lead pipe to buckle in bending, we do not believe that it is practicable to handle cables of larger diameter and weight. The consideration of these facts led us to decide that our ducts should hereafter be 3 inches.

We are using nothing but the lead covered type of cable, some of which has been in service underground for four years and is still in good condition. Of the cables which were laid four years ago, those covered with pure lead appear to be more than half eaten through. One that has been drawn out during the writing of this article has been underground for two years and is badly corroded, there being holes eaten in it in many places nearly one-sixteenth of an inch in depth. Of the cables furnished by the Western Electric Company at the same time, in which there is a small percentage of tin mixed with the lead, the corrosion is very slight, and we are led to believe that cables covered with this alloy will last from three to four times as long as those covered with pure lead. We believe that if in addition to the tin the cables were drawn through a bath of gas tar or asphaltum, then covered with a good stout braid and run through the gas tar or asphaltum again, the cables would be practically imperishable, so far as the outside covering is concerned, and it is a question whether this additional expense would not be justified by their increased length of life. It is certainly worth the trial.

The air-tight terminals which were put on all our lead cables more than a year ago, appear to have removed all the difficulties which we formerly had at that point, and the tests of our cables, making due allowance for temperature, etc., show that there is no deterioration during the past year.

Of the cables mentioned by me last year, one of 7,180 feet, containing 100 wires, twisted indiscriminately, manufactured by the Western Electric Company, has been reduced by the change to the new central office to 6,344. Tests made Aug. 16, 1888, give an insulation of 800 megohms; capacity, .22 microfarads; resistance of the conductors, 43¼ ohms per mile. The conductors are .038 inch in diameter, insulated to .088 inch. For a time during the past year all the conductors were in service, but recently the trunk lines to the Bedford office have been taken out, and there are now 80 wires working through it. The condition of this cable in regard to cross-talk is the same as last year. That is, it is not bad enough to prevent its use.

The cable manufactured by the New York & New Jersey Telephone Company, with 100 wires, twisted in pairs, has been reduced to 6,117 feet. Tests on August 19, 1888, give an insulation of 89 megohms per mile, capacity .275 microfarads, and the resistance of the conductors 48 ohms per mile; temperature in both these cases being, in the air, 80 degrees, and of the water from the hydrants 73 degrees. We assume that the temperature of the water from the hydrants is the temperature of the air in the conduits. Seventy-four wires are working through this cable, and the cross-talk is no worse than last year, and is not so bad as to prevent its constant use. In both cases all the dead wires are kept grounded at the cable terminals.

The greatest length of cable we have now underground is 11,800 feet, between our Bedford street and Williamsburgh offices, consisting of 100 wires, twisted in pairs, the pairs broken up at all the splices; conductors .035 inch, insulated to .075. The insulation of this cable is 99 megohms per mile; capacity, .26 microfarads; resistance of the conductors, 47 ohms per mile. Seventeen conductors in this cable are in use for trunk service between the two offices, the rest of the wires being grounded close to the terminals at both ends. The cross-talk in this cable is very slight, and is indeed less than in the Western Electric cable of 7,000 feet. We received complaints from both these offices that the talking by subscribers through this cable was difficult and unsatisfactory. A special investigation of these complaints at the points they

originated demonstrates that the difficulties complained of are not in the cable, but rather in the condition of the transmitters and instruments in the various offices and carelessness of the subscribers. Considering this cable as a whole, two miles in length, its electrical qualities are: Insulation, 50 megohms; capacity, .53 microfarads; resistance of conductors, 94 ohms. We are inclined to think this is about the limit of good working in that type of cable, and that the complaints we are getting about the service over it are due to the fact that it loads up the circuit so that there is no margin for any deficiency in the subscribers' circuits connected to it; whereas, if its efficiency were higher, there would be a margin to cover such defects, and complaints would be prevented. There is no doubt that the reduction of the cross-talk and the increase in the capacity is due to the fact that 83 of the 100 wires are grounded at the terminals, and that when the whole cable is put into service, this condition of affairs will be changed more or less; that is, the capacity will diminish and the cross-talk will increase.

It was a consideration of the difficulties to be encountered in the use of greater lengths of this type of cable, which the above experience emphasizes, that decided us during the past year to make a special cable for our trunk lines, doubling the weight of copper and thickness of insulation. This resulted in our ordering three miles of cable, conductors .052 inch in diameter, insulated to .125 inch, 60 wires laid up indiscriminately, and during the past two months two miles of this cable or 10,560 feet, have been put up on the elevated railroad structure, connecting the Brooklyn central office with the Bedford central office. The insulation is between 1,200 and 1,500 megohms per mile; capacity, .27 microfarads, resistance of conductors between 21 and 22 ohms per mile, at a temperature of 74 degrees. This cable, though of the same length as the one between the Bedford and Williamsburgh offices, just mentioned, gives surprisingly better results, the cross-talk being very slight and the volume of sound full and strong. Forty of these wires are grounded at the cable terminals, and 20 are in active service.

There does not seem to be anything in the electrical measurements to indicate what causes the difference in the practical working of the two cables, but the results are gratifying and seem to plainly indicate that increasing the weight of the copper and thickness of the insulation is a step in the right direction, and I am inclined to think that grounded trunk wires of this last type may work successfully between our various Brooklyn offices, the distances between which do not exceed two and one-half miles.

All the new cables we have used this year have been of 102 wires, or 51 pairs, twisted, laid up in regular cable form, in alternating reverse directions, conductors .035 inch in diameter and insulated to .125 inch. The insulation of these cables when placed in position underground ranges from 1,500 to 2,000 megohms, capacity from .17 to .18 microfarads, and the resistance 52 ohms per mile. We believe that this type of cable will fulfill all the conditions required in our underground work, but at the present time we have no length sufficient to give actual working results.

The transition period between grounded and metallic circuit systems will be very troublesome and annoying, and may last several years. It is our intention in ordering the type of cable just described to make provision in the man-holes for joining the sections together by devices which will enable the joints to be opened readily without cutting the cable and the pairs broken up in order to prevent cross-talk on grounded circuits, and, at the same time, allow of access to them for straightening them through when twisted metallic circuits are required. The necessity for getting at the joints in this way from time to time, and the space required to accommodate connecting boxes, is another argument in favor of large and commodious man-holes.

The durability of lead pipe, with a slight mixture of tin, the maintenance of a uniform and high insulation, together with uniform resistance of conductors after four years of service, are indications of length of life that are very encouraging.

Up to the present time we have met with no serious accident in our underground work, either from explosions of gas or the men being overcome with foul air. We believe it quite likely that gas is not as plentiful in the streets of Brooklyn as it is in many other cities, and therefore the accumulation in the ducts and man-holes is not so great; but we have been very careful not to spare any precautions that would insure our safety.

The Dorsett conduit, of which we have five miles, with ducts two inches in diameter, has proved to be very unsatisfactory, and the ducts, on account of inequalities at the joints, will only permit of a cable an inch and a quarter in diameter being drawn in. This reduces the capacity enormously, and is, therefore, a source of inconvenience to us.

It is plainly proved that the use of underground wires reduces the margin of good working very largely and will, therefore, require that extraordinary care must be taken to bring the service to its highest efficiency at all other points.

The most fruitful source of our trouble is the transmitter and battery, and while there have been very great improvements during the past year or two, there is still room for much more improvement before we reach perfection. The numerous contacts, in the magneto-bells and other apparatus, need especial attention and care, and platinum should be used wherever possible.

Another source of trouble is carelessness in running the wire from the insulator outside the building to the instruments in the building. The writer knows of many cases where the subscriber's wire is run through the window casing with the ordinary cotton covered wire and but little care taken in the inside of the building to keep it away from possible dampness.

As the mileage of underground wire increases, these and other faults, now overlooked, will become more and more apparent, and the expense of maintenance and inspection will be largely increased. There is only one way to bring back the easy working margin we have enjoyed on pole wires, and that is by the use of metallic circuits, and the sooner we get down to that basis, the better it will be for the service.

The following shows the actual extent of our underground work on Sept. 1, 1888:—

	Miles.
Length of conduit	15.17
Length of duct	105.5
Length of cable	22.93
Length of conductor	2,053.8

Nineteen hundred and thirteen subscribers are working through underground wires, using 1,229.9 miles of wire.

THE TELEPHONE EXCHANGES FOR THE CITY OF NEW YORK.

BY E. F. SHERWOOD.

THE Metropolitan Telephone and Telegraph Company has 7,300 subscribers, operated by eleven exchanges which are furnished with the following systems: John, Thirty-ninth and Harlem exchanges use the Western Electric multiple; Pearl, New, Nassau, Murray and Twenty-first street exchanges use the Chinnock system; Spring street, the improved Chinnock system, adopted by Mr. Jos. P. Davis, formerly general manager of the company; Fulton and Beaver street exchanges use the Law system. The John street exchange has 799 subscribers and 40 trunks distributed among them. The Thirty-ninth street exchange has 1,108 subscribers and 39 trunks, and Harlem has 374 subscribers but no trunks terminating outside of the trunk sections. The reason that we have trunks at the two former exchanges among the subscribers is to connect the system with points not accessible or convenient to reach with trunk calling wires.

To operate the boards during the busiest hours requires the following number of operators: John street, 14 operators, 57 subscribers per operator; Thirty-ninth street, 21 operators, 52 subscribers per operator; Harlem, 6 operators, 62 subscribers per operator; but counting the trunk wires according to the business done over the average subscriber's wire will be equal to adding 73 subscribers to John street, and 70 to Thirty-ninth street, thus increasing the average at John to 62 and at Thirty-ninth to 56. The reason we have a greater average at John and Harlem is that they are situated in the centre of business district, while Thirty-ninth street being a manufacturing and residence district a larger portion of the business is trunk.

We are using what we term trunk calling wires between the various exchanges, one terminating at John street and the other at Thirty-ninth street, for calling all trunk connections to the exchanges named.

There is an average of 3,000 connections per day called over each of these wires, and as each connection is ordered off again the number of orders is increased to 6,000. All of this work is done by two operators at each of these exchanges, and could be done by one if a whole section of the board was within her reach. We divide the trunks, one half being used for receiving and the other half for sending. Those we receive on are not multiple through the board, but end in cords and stand open at all times except when in use. When a number is called on any given trunk the connection is immediately made and is ready for ringing, this being done by the office calling, as we make the office where the call originates responsible for the connection. If the number called is busy we throw battery on the trunk, dropping the annunciator as a signal. We find this system very advantageous, as there is no delay in calling or clearing trunk connections and the service is made prompt, as shown by 10 trunk connections made and conversations started with subscribers in six and one-half minutes.

At the exchanges which have the Chinnock system, each operator at the cases answers 100 subscribers and completes all local connections, using a local calling wire and a set of local trunks, which connect all the cases together. The calls for trunk connections are written on slips of paper and passed to the operators who control the trunks to the various exchanges. Ten trunk connections were made and conversations started through this system in twelve and one-half minutes.

The Fulton and Beaver street exchange have, together, 410 subscribers, and are operated by nine operators and one chief operator. All local connections are completed by the operator

who receives the call over the calling wire, and trunk connections are completed by the operator at the exchange for which the subscriber calls. The Law operator simply connects the subscriber's wire with the trunk wire and rings down the annunciator, when the operator answers and ascertains from the subscriber the number wanted. Ten trunk connections made through the Law system were completed and conversations started in 4¼ minutes, ten local connections in 2¾ minutes.

The number of trunk wires connecting the exchanges in New York city is 532 and average 60 connections per day, and as this average could be increased to 70 per day, the number of subscribers could be increased 600 without increasing the trunk facilities. To other exchanges we have 187 trunks, and with those the service is quite satisfactory, and especially so with the new Brooklyn exchange of the New York and New Jersey Telephone Company, and the service is prompt and satisfactory in every particular.

By the consolidation of the seven exchanges in the new exchange at 18 Cortlandt street, 206 trunks which connect these exchanges will be abolished, and the number of trunks to all other exchanges may be reduced, for the total number divided among the seven exchanges will not be required when they are all accessible to an operator in the new exchange. The new switchboard at No. 18 Cortlandt street will soon be completed and the consolidation of the seven exchanges made. It is wired for 5,100 subscribers and 900 trunk wires. The subscribers' operators will attend to 50 or 75 wires, according to the business done at different sections of the board. Trunk calling circuits to the other exchanges will be in operation, each receiving trunk operator attending to 50 wires. The local battery of each operator's outfit will be two cells of storage battery, one to be in use during the day and the other at night. The one in use during the day will be charged at night from the main storage battery, and the night battery will be charged from a dynamo during the day. All wires will approach the exchange through the underground system, the underground cables terminating in the cellar. From there they will be carried to the distributing board in the exchange by 334 conductor cables. The consolidation of the several exchanges will be beneficial in many respects. The service will be improved, the great volume of "sent" trunk business will be reduced from 20,000 to 8,000 connections, and the running expenses of the exchanges will be reduced about $2,700 per month.

One thousand five hundred and twenty-seven miles of wire are now underground, and 2,784 separate wires are altogether or in part so working, most of which give general satisfaction. The underground facilities are rapidly increasing, 18 miles of 102 conductor cable running from 18 Cortlandt street to various points are now completed, and will be used when the exchanges are consolidated. Eight and three-quarter miles of the same cable will soon be run for trunks from 18 Cortlandt street to the other exchanges, thereby making the trunk service from this exchange entirely underground and doing away with the delays and expense of crossed and broken trunks, and will do away with the danger of crosses with wires carrying a heavy current, which proved so costly in connection with the burning of the Thirty-ninth street exchange, on which a few remarks may be of interest.

On May 23d the Thirty-ninth street exchange was set on fire by a cross with a wire carrying a heavy current, and one and one-half sections of the board were burned out. The work of restoring the Western Electric multiple board after it has been burned and saturated with water can only be appreciated by those who have had to do it. In order to straighten out the wires it was necessary to make 1,260,000 tests, to splice 9,600 broken wires, to replace 16 cables which were destroyed from the switchboard to the cupola, and dry out the saturated portion of the board. The work of getting the lines in complete working order was delayed by the accumulation of line trouble while the troublemen were working in the exchange, but the switch-board and all the lines were in complete order two weeks from the date of the fire.

THE TELEPHONE.

BY DR. S. M. PLUSH.

No discovery or invention was ever born at a time when the world was more ready to receive it than that of the telephone, notwithstanding which, great talent, perseverance and wealth were necessary to its successful introduction. The uncertainty which unfortunately hedged it about gave rise to temporary work and machinery, which has simply been renewed to the present time, and to-day the vast telephone system of the country is but a network of unreliability and temporary make-shift. Even the head centres or main exchanges (with but few exceptions), representing untold labor and expenditure of large sums of money in machinery and apparatus, are held by but a feeble tenure.

At that period but little time was given for consideration, and a forecast of what the future would be was difficult. The growth of telephone plants was without a parallel in any industry; the demands made upon them were greater than their means of supply; competent labor was not in the market and efficient machinery had not been devised.

The difficulty of meeting the requirements of a large number of subscribers at a given point early presented itself, and gave rise to a number of small exchanges, even in the most populous districts. This, together with the resistance on the part of the public authorities to the erection of necessary conductors, set the seal of fixidity upon what is manifestly a great hindrance to good and reliable service, while in nowise conducing to economy. The expense for rents, light, fuel, trunk lines, and the introduction of so many additional connections into circuits call loudly for aggregation, and we believe the tendency is in this direction, and the time not remote when trunk lines will be known only as a means of reaching points far distant.

Probably the greatest drawback to-day to the complete development of our telephone systems is a growing tendency in legislative bodies to regulate prices to be charged for service, which, in effect, is simply to paralyze its growth and efficiency. Were the telephone the only means of communication, some regulation might be wise; such, however, is not the case—we have the postal, telegraph, and messenger service, each filling its own peculiar sphere, as regards reliability, speed and cheapness. The telephone should, so far as practicable, combine all of these features, but neither should be sacrificed to the others; to regulate either must be at expense of the whole.

When the field is once open to competition, that company which rigidly adheres to reliability and promptness in its service will not suffer through paucity of its finances.

Nothing in my opinion has operated more to the disadvantage of both the telephone companies and their subscribers than cheap rates. Many, through this means, have been induced to become subscribers to an exchange who have no real need for the facilities it affords. This lends a tone to their business, it is true, and serves in a measure as a card of respectability. Their place at once assumes an imaginary importance, and if there is any one thing that delights them more than another, it is having some real or fancied business with a leading and substantial firm. This they manage to have at frequent intervals, thus taking the time and monopolizing the wires of others, to their detriment and absolute loss. Important business is thus delayed and the value of the exchange materially lessened.

Busy houses to-day find it necessary to have some one in constant attendance at the telephone, and yet many calls are so delayed as to be useless. It is but fair, therefore, that their interests should have as many safeguards thrown around them as possible; that their conveniences and time may not be engrossed by frivolous questions in which they have no interest whatever. In other words, an exchange may be so large as to be comparatively worthless.

Constant effort towards speed, both of connection and disconnection, is being made, thus making a greater number of calls in a given time possible, and thereby removing the limit, which would otherwise soon be reached; but this limit must ultimately be reached, and what then? Even now requests for discrimination in making connections are not uncommon.

At the present growth of our largest exchanges the time must come when a more select means of communication will be demanded by the business public. That is, an "exchange" for business ("select," if we may so term it) where a party to become a subscriber will not only be required to pay his annual rental for service, but must hold a certificate of membership as well.

George Eliot remarks, that we began life, knowing little and believing much; a few years of experience, however, and in many cases the quantities are inverted. This aptly applies to every man connected with electrical science and mechanics, particularly the telephone and its environments. We live to-day in the same atmosphere we did ten years ago; nothing has materially changed, except ourselves, and we only in credulity. True, our experience has been great and varied, and has taught us in some instances how not to do it, and by this slow but certain method of evolution may in time teach us how to do.

It is difficult for us to realize that we are gradually making a history, and that the records of the great telephone must eventually be written; that we are each of us contributing thereto; that no matter how small a factor each may be, he is a part, and that at last his individual size must be determined by the magnitude of the whole. It behooves us, therefore, to see that the foundations of the telephone, which are now being laid, shall be solid and firm, that every right, every franchise, shall be permanent, every structure substantial, every centreing point immovable and every method correct, and to this end the energies and intelligence of those associated with the telephone can be profitably directed.

.... THE future system of electric railway distribution will be one in which the current will be transmitted from the generating station at a high electromotive force over well insulated main conductors, and in which the current will be converted into a lower electromotive force and supplied to the motors by means of sectional working conductors at a safe and economical working pressure.—*Elias E. Ries.*

LIGHTNING.[1]

BY S. A. VARLEY.

(Continued from page 400.)

I FEEL the title that heads this article must seem somewhat of a misnomer, and as a matter of fact, I wanted to alter it when it was too late to do so; but it was the observation of the action of a lightning discharge on a telegraph circuit in 1856, which directed my attention to magnetic inertia, the source, as I believe, of all the so-called self-inductive phenomena, and it was the late lectures on the protection of buildings from lightning, by Professor Lodge, that led to the writing of the article, and hence the title which was chosen.

By directing attention, as I have now done, to the important part which the inertia of magnetism plays in dynamos, I think I may claim to have made a step in advance, for I consider I have linked to a certain degree the mechanical force developed in the steam engine with the internal forces in the mass of matter composing the machine, and this, as far as I know, has hitherto never been attempted to be done; further, I think I have thrown light on the *modus operandi* of the transmission of energy by dynamo machines.

In a previous portion of this article, I have likened the development of energy in a dynamo to a bombardment of a mass of matter which produces heat in place of motion of the mass; but what I wanted to convey would, I think, be more popularly explained by a further illustration. Assume we have a large mass of matter suspended in the atmosphere, the attraction of the earth being balanced and neutralized. If force be applied, this mass will be set in motion, the rate of motion progressing directly as inertia is overcome. After motion has been imparted to the mass, it will continue to move unaided, as force is indestructible; but the friction of the atmosphere causes a certain amount of skin resistance, and force sufficient to balance this will have to be applied to maintain the motion, such force being wholly consumed and dissipated in the form of heat; and so it is when an electric circuit is closed through the insulated wire of an electro-magnet, the inertia of magnetism has to be overcome to allow of the motion of the electric atoms (if I may so term them) resident in matter, and all that is necessary to maintain the electric motion which has been set up is energy sufficient to balance the resistance that all conductors oppose to the transmission through them of electric motion, a resistance analogous to the skin resistance of a mass of matter moving through a viscous medium.

If the steady flow of the electric atoms be suddenly checked, then the inertia of magnetism, the equivalent of stored up energy comes into play, and acts in a precisely analogous manner to the stream of a water ram when its flow is suddenly checked, the total amount of energy becomes imparted to a smaller number of the electric atoms, and consequently the electric potential is increased, such potential being increased directly as the amount of resistance opposed in its path. Magnetism and electricity appear to me to be separate forces, and they are so intimately associated with what we understand by the word matter, that the older I get the more I regard them as being a species of matter, if not actually part and parcel of it. Now, if we regard electricity and magnetism as distinct entities or atoms, then, I think, we can obtain a general comprehension of electro-magnetic phenomena, and the *modus operandi* of the transmission of force by supposing iron and magnetic substances to possess a much larger number of magnetic atoms than non-magnetic matter, and that directly as the number of magnetic atoms in a conductor, so is its resistance to sudden atomic motion or polarization. The mass of iron composing a dynamo armature possesses a very much larger number of magnetic atoms than the insulated copper wire surrounding it, and therefore when the armature is revolved through the magnetic fields of alternate direction, the mechanical force of the engine is deflected, as it were, and instead of overcoming the inertia of the magnetic atoms and magnetically polarizing the armature, it sets the electric atoms resident in the convolutions of insulated wire in motion in alternate directions instead, and conveys along with the electric currents developed the energy consumed in imparting motion to the dynamo, in a somewhat parallel manner as when an India-rubber ball is thrown against a wall, and its direction of motion, as well as the energy imparted to it, is altered.

If an electric circuit be closed through a straight conductor, the conductor exhibits magnetic phenomena, iron filings are attracted, and a magnetic needle subjected to its influence and free to move, will take up a definite position which has reference to the direction of the electric current. If the conductor be insulated with cotton or silk and wrapped so as to form a solenoid, there will be an increase of magnetism produced when the electric circuit is closed through it. This arises from two causes: 1st, the magnetism developed is concentrated in a smaller space; and 2d, as a consequence of this concentration, arising from the greater contiguity of the coils, they are brought more under the influence of one another and act inductively and thus enhance the magnetism produced.

It will be observed if the circuit through the solenoid be divided, the spark produced in the act of breaking contact will be a heavier one than occurs if the battery wires be simply brought together and separated without including the solenoid in circuit.

If the solenoid be placed in the interior of a second solenoid and the circuit of No. 2 solenoid be closed through a galvanometer, a momentary deflection will be observed on closing No. 1 solenoid in the battery circuit, and a second momentary deflection of the galvanometer needle, but in the opposite direction, will be noticed when the battery circuit is broken.

It will be further observed that the spark produced by the division of the battery circuit through No. 1 solenoid is greater if No. 2 solenoid is open at the time, than the spark produced if No. 2 solenoid circuit be closed.

If a cylinder of soft iron be inserted in the interior of No. 1 solenoid, then all the phenomena which have been just described will be observed, but in a greatly enhanced degree. Further, it will be observed, that if the circuit through No. 1 solenoid be opened and closed rapidly, or if currents be sent through it in alternate directions, the soft iron core will be found to have become heated, and that the heat developed will be greater if the circuit of No. 2 solenoid be kept open, than the heat that is developed when No. 2 solenoid circuit is kept closed.

If the iron cylinder be replaced by a core composed of fine iron wires, then all the effects above described will be still further enhanced, with the exception of the production of heat in the iron core which, if not now actually imperceptible, will be found to be very much reduced.

I need not enter into detail as to how the phenomena referred to are produced, for what has been stated is common knowledge to most of your readers; but what I do want to direct attention to is that there is too great a tendency for those trained in the schools to regard such phenomena separately, instead of grasping them as a whole and perceiving that they are simply incidents arising out of first principles.

For example, scientists speak of extra currents, secondary currents, and Foucault currents as distinct from one another, and we have had lately added to this list self-induction, and new terms suggested to be used in connection with it.

Now I venture to assert extra currents, secondary currents, Foucault currents, and self-induction are produced in the same way, and that they are all referable to the inertia of magnetism.

Professor Hughes' researches demonstrate, as might be naturally expected, that the conditions most favorable for the exhibition in a conductor of what is called self-induction is the exact converse of that for the development of magnetism in a mass of soft iron.

A solenoid of copper wire will, I venture to say, exhibit more powerful self-induction than a straight wire, and for the same reason that more magnetism is developed by a helix than a straight conductor.

For the development of what is termed self-induction in a straight conductor, a cylinder is the best form, as the molecules of which it is composed are in closer contiguity in a cylinder than in any other shape, and consequently the conditions for magnetic induction between the molecules are more favorable. On the other hand, a ribbon conductor is the one in which the molecules are separated to the greatest extent, and therefore the conditions are the most unfavorable for magnetic induction between the molecules.

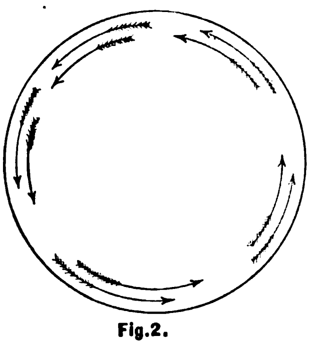

Fig.2.

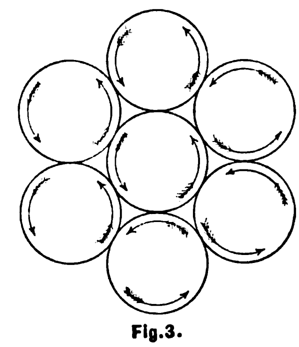

Fig.3.

If an electric current, which may be termed the magnetizing current, be sent round a soft iron cylinder, as a consequence of the inertia of magnetism, a temporary current is set up in the iron and passes round it in an opposite direction to that of the magnetizing current, and a solid cylinder of iron is the best form for favoring the development of such temporary currents.

If the cylinder be replaced by a bundle of iron wires, the temporary currents set up round the wires pass each other in opposite directions and neutralize one another, and the tendency to form such currents is consequently checked.

If an electrical current be sent through a cylindrical conductor, rings of magnetism will be formed at right angles to the direction of the current, and these rings, which we will call magnetic currents, will flow round in a uniform direction.

If, however, the solid conductor be replaced by a bundle of

1. From The *Telegraphic Journal and Electrical Review* (London).

conductors formed of wires of small sectional area, then the tendency to form magnetic currents will be greatly interfered with, as the magnetic currents formed in each wire will be in the opposite direction to that of its neighbor, or more correctly, will pass one another in opposite directions and neutralize one another. Figure 2, represents a cylinder of iron in the act of being magnetized, the arrows indicate the temporary or, as they are termed, the Foucault currents flowing in the interior.

Figure 3, represents a bundle of iron wires in the act of being magnetized. It will be seen by the arrows that whatever currents are set up oppose one another, and therefore tend to stop their formation.

Now if figure 2, be regarded as a cylindrical conductor, the arrows will indicate the magnetic currents flowing in a uniform direction, which develop magnetism also in a uniform direction, and favor self-induction; and if figure 3 be regarded as a conductor composed of a bundle of wires, it will be seen that the tendency to form magnetic rings is prevented, as the direction of the magnetism which would be developed in any of the conductors would be balanced by that developed by its immediate neighbors, and therefore the conditions are not favorable for magnetic polarization, or, as it is termed, self-induction.

I think it has been now fairly shown that what is termed self-induction is magnetic inertia, and that magnetic inertia in a conductor is manifested directly as the quantity of magnetic matter brought under the influence of the *whole* of the electricity set in motion *throughout* the conductor.

That for this reason a ribbon conductor has less self-induction (magnetic inertia) than a cylindrical one, and a straight cylindrical conductor has less inertia than the same conductor when formed into a solenoid, and, further, this solenoid has less inertia than the same solenoid when a bundle of iron wires is placed in its interior.

We know the conditions which favor the development of magnetism, and these conditions harmonize throughout with the conditions which are found to favor the production of the phenomena attributed to self-induction.

If self-induction were due to electrical inertia, as Professor Lodge and others seem to believe, then it would be difficult to assign a reason why a ribbon conductor should not exhibit it in as great a degree as a cylindrical one.

The inertia of matter is directly as its weight, and electric conduction as the weight of the conductor multiplied by its length, the shape of the conductor (assuming it to be a uniform section) not influencing the conducting power in any way. Now, if self-induction were due to electrical inertia, it might be fairly expected that it would so far harmonize with electric conduction and material inertia as not to be affected by the shape of the conductor; but grant, for the sake of argument, that the shape may have an influence, then the self-induction manifested should not be affected in any way, whether the conductor be in a straight length or formed into a solenoid. Now I have never actually tried whether a conductor in the form of a solenoid will exhibit the so-called self-inductive phenomena in a greater degree than the same conductor when straight, but I will venture to stake my reputation as an electrician that this will be found to be the case, and if it be so there can be no escaping from the conclusion that self-induction, as it is called, has its source in the inertia of magnetism, and is magnetic inertia pure and simple.

What is understood as the development of electricity, is generally attributed to an internal movement in the conductor which sets in motion the electricity associated with matter throughout, the conductor energy being locally dissipated directly as the resistance of the conductor through which a given quantity of electricity is passing. I myself am strongly of opinion that electric conduction is atomic as distinguished from molecular movement. There are reasons that lead me to conclude that electricity and gravity are forces as distinctly separate from one another as the material elements with our present knowledge would seem to be, and, therefore, gravity and electricity are not *directly* convertible.

There are reasons also for believing chemical affinity and electrical attraction are one and the same thing, and are concerned in the organization of matter and the formation of the atoms into molecules. Cohesion and gravity, on the other hand, would appear to have their origin in a common principle and to deal with matter after it has been formed into molecules binding molecules together and attracting matter in the mass bodily.

Familiar as we seem to be with matter from constantly being brought into contact with it, we know really but little of its constitution; the same may be said of inertia, motion, force, and time, terms in constant use, and the effects of which we come face to face with almost every moment of our lives.

If our scientific schools would only break fresh ground by making researches into the nature of such elementary principles as I have mentioned instead of devoting their lives to the microscopical measurement of data already known, and constructing with the aid of the scientific mechanician more and more perfect measuring instruments, as if the end of science were measurement, then I venture to think our progress in the acquisition of *real* knowledge would be much more rapid than it is.

By far the greater part of the communications brought under the purview of the scientific societies are simply additional literature which often tend to confuse plain issues and by the very mass of elaboration and detail make the acquisition of scientific knowledge more and more difficult. What struck me most at that very interesting exhibition of the late loan collection of scientific apparatus, was the apparatus of Faraday and models of that of Ampere, the whole of which stood on two small tables and could have been reproduced for a cost of a few pounds.

The simple apparatus of Ampere and Faraday was surrounded by the costly accurate apparatus of modern times, the whole of which, if regarded from a purely scientific standpoint, had been chiefly designed to measure, and only to measure, the work accomplished by men of the calibre of Faraday and Ampere.

All we know of motion is that it is relative to matter and that it involves at the very least two atoms, for there can be no such thing as motion in reference to absolute space. I have been disposed to regard motion as a combination of matter with external force or energy of some form, and inertia as the storage of the external force by matter that involves time, an entity we really know next to nothing of.

If the question be asked what is force, our scientific schools have a ready answer. They will tell us forces are modes of motions, and would seem to think we ought to be satisfied with such an answer, which is really no explanation whatever.

For my own part, when I have sat under a certain popular ritualistic scientific preacher or master of style, as he is commonly termed, and observe the very vestments in which he has dressed, his experiments appear to have received more attention at his hands than the truths he professes to be so anxious to inculcate. I could not help my sense of the ridiculous being excited when I have heard him enlarge from his pulpit on the infallible rock on which science is based, and the breadth of view which distinguished his own particular school as contrasted with another school of thought for which he does not disguise his contempt, and I have been unable to resist smiling when he has afterwards given his audience to understand that the nature of force is well understood and explained by the statement that they are modes of motion.

Whoever it was who coined the phrase, "heat is a mode of motion," must, I always feel, have had a lively appreciation of the scientific uses of the imagination.

In a certain sense I confess this phrase may be regarded as involving a truism, seeing every act performed is associated with what we express by the word motion, and what we understand by the word force is largely concerned in bringing about such motion; but if we analyze the phrase, it will be found to be merely a string of words, and nothing more or less than the concealment of our ignorance by the assertion of a dogma; and let me point out what is, I think, not recognized as much as it should be, that all scientific phenomena, if traced back to first principles, will be found invariably to be based on observations of a something which is neither more or less than a dogmatic utterance, and would be correctly expressed by the words, "thus saith nature," a phrase very similar to that which frequently occurs in the sacred writings.

Dogmas have their use undoubtedly, and the phrase, "heat is a mode of motion," shines with a reflected glory, simply because some of our most eminent scientists have been content to accept the dogma as a rallying point or flag; and it is the work they have accomplished fighting under this banner, and this work *only*, which has given a value to the phrase, much in the same way as that given to the tattered rag some distinguished regiment carries into battle, and around which men fight and die, and which in the end finds deservedly a resting place in our cathedrals, because it symbolizes that which distinguishes men among men, and man as man from the greater part of creation.

I must ask your readers to forgive this digression, the only excuse for which I can plead being that it seemed to me to be wanted to be said. Professor Lodge has stated that electricity is not energy, but one of the vehicles by which it can be conveyed, and I have myself, on the whole, been disposed to adopt this view; but some years ago, as the outcome of reasoning on certain experiments, I formed a theory, of which I made a note, which regarded electricity as energy. I, however, put this theory aside, partly because I am so strongly impressed with the feebleness of the human intellect to grapple with the phenomena presented to our gaze by the world of mystery in which we dwell, and partly because, in my opinion, there is too great a tendency to theorize and speculate; but as I have been writing this article the theory I have referred to will keep obtruding itself, and as it now seems to me to harmonize with the general direction of thought of the present time, I propose to briefly describe it. At different periods of my life I have thought I had obtained evidence that time might be considered to be a force; the evidence collected has, however, broken down invariably on more mature reflection. But, although I am disposed now to think that time cannot in any proper sense of the term be regarded as a force, it seems to be certainly a connecting link between the forces, and to have an important influence on them—for example, if a given amount of

energy in the form of force of low potential be brought to bear on a mass of matter suspended in space, the whole of the energy, with the exception of a percentage so small as to be negligible, will be absorbed by the matter and converted into motion of the mass; but if the same amount of energy in the shape of force of higher potential be applied, the percentage of energy not converted into bodily motion will no longer be negligible; and if this given amount of energy be brought to bear on the mass, in the form of force of much higher potential, nearly the whole of it will become converted into heat, and the motion now imparted to the mass will be the negligible quantity. We see from what has been above stated that time is capable of connecting energy with matter in such a way as to determine whether it be simply transmitted or converted at once into local work.

Heat and energy are convertible terms, and there is one case, and *one only*, that I am aware of, where the energy appears to be converted directly into electricity, and that is in the thermo battery. The fact that electricity appeared to me to be produced in this instance in an altogether different way, led me to try some experiments on the development of thermal currents, and the conclusions I came to harmonize with what I believe to be the generally accepted view, that the conditions the most favorable for producing thermo electricity are those that favor a rapid absorption of heat and its rapid radiation through the thermopile; and there seemed to be no escaping from the conclusion, that in a thermopile we have an example of the direct conversion of energy into electricity, and if so, then electricity must be something more than a vehicle of energy and would appear to be a form of energy.

Now if we accept the dogma that heat is produced by an atomic bombardment producing in the matter bombarded atomic motion, it seemed to me electricity might differ from heat simply in being a still more rapid motion, and that thermo currents were produced in a somewhat analogous way to that which occurs in a water ram where energy of low potential becomes converted into energy of a higher potential at the cost of a somewhat wasteful expenditure of energy.

Assuming the views I now venture to promulgate to be correct, and that electricity differs only from heat in being a more rapid atomic motion than the potential or energy of a current would be directly as its rate of motion, and we should have a simple explanation of what I believe to be the fact, that a lightning discharge cleaving its way through a space, it may be, of more than a mile of air, occupies no more time than the spark which discharges a Leyden jar.

The production of heat by electricity would be also accounted for in a natural manner, as when the rate of motion was retarded by resistance it would assume the form of heat, and the retardation would be the measure of the energy expended in breaking down such resistance, whether it be a conducting wire of small sectional area, a glow lamp, or electric arc, or a space of air.

I would further point out the theory now propounded which has been gradually evolved out of reasoning upon experimental observations, and which has forced itself unbidden on my attention, seems to me to link together in one continuous train or natural order of sequence the data already known in connection with the action of gravity, the conversion of motion into heat, the development of electricity, and the transmission of energy by means of the dynamo. For example, when a stone falls from a height energy is imparted to it by gravity combined with time, such energy being a function of the weight of the stone multiplied by the time gravity has been free to act upon it.

When the stone becomes suddenly arrested the energy of motion acquired is given out in a much smaller interval of time than that consumed in its production, and it becomes converted into internal motion or heat, a more refined form of energy and of a higher potential, using the term potential to express rate of motion, and this more refined or purer form of energy, when it is arrested by coming into contact with magnetic inertia, becomes converted into electrical or still more rapid motion, the rate of motion of the electric atoms being determined by the amount of energy arrested and the resistance of the conductor through which the electricity is transmitted.

Having now launched my little theory, and given the reasons for the faith that is in me, I leave it to others to deal with; it may be to explode, to put it aside, or perhaps to ignore altogether.

I now propose to examine briefly statical charge, energy, and the relation of the earth to statical and dynamical electrical phenomena, and afterwards to make a few comments on Professor Lodge's experiments.

None of the theories give a very satisfactory explanation of statical charge, and until we know more respecting the real nature of electricity we can scarcely hope for one.

I confess to a certain mental reaction in favor of the Franklinean theory; but it appears to me nevertheless that statical charge, on the whole, is more understandable on the supposition that what we are in the habit of terming positive and negative electricities are two distinct entities.

Franklin's hypothesis assumes the pumping out of electricity on one side of the dielectric, and its accumulation on the other side, producing a sort of reorganization or re-arrangement of the sum total of the atoms and forces which go to make up what we term matter, and in this way bringing about a strained condition.

Now we are only cognizant of electricity and energy as associated with matter, and we cannot readily grasp the term energy in any other sense than as implying activity; and if energy be motion, then to talk of it as being in a statical condition seems to be a contradiction of terms. We can, however, with less mental difficulty realize energy being balanced by energy, and thus bringing about a condition of equilibrium.

We have an example in a revolving disc, where matter is subjected to force in such a way that the energy exerted throughout the matter composing the disc is in opposite directions. Now, although a rotating disc is not an explanation, it is an illustration that helps us forward in the direction of an explanation of statical charge.

In a revolving disc we have motion imparting energy to the molecules of the disc tending to separate them one from the other; but at the same time, the disc, as a whole, is in a condition of equilibrium, and behaves like matter at rest in reference to external forces, such as gravity, etc.

As the disc has been subjected to a single force, and force is indestructible, the energy imparted cannot dissipate itself by discharge, and the disc continues to revolve, the energy dissipating itself gradually in the form of heat produced by friction at the bearings and the skin resistance of the atmosphere.

Were the energy, however, of a dual character, we could imagine the disc being brought suddenly to a state of rest by the union of the two forces, accompanied by a rapid dissipation of energy, such as we have experience of when a Leyden arrangement is discharged.

The query suggests itself: Can statical charge be looked upon in the light of a storage of energy?

Maxwell has stated: "The total energy of any material system is a quantity which can neither be increased nor diminished by any action between the parts of the system, though it may be transformed into any of the forms of which energy is susceptible."

Accepting the above definition, the phenomena of energy must be attributed to a temporary shifting of the energy forming part of the system; and if a Leyden jar be regarded as a complete system, then statical charge may also be regarded as a production of energy of position, or storage of energy, or more correctly, perhaps, as an approach to it, for we have in the case of the statically charged jar internal forces displaced but not removed, and the organization of the matter composing the Leyden arrangement is not actually altered, but only tending to be so.

If we place two platina plates in a cell containing water, or acid and water, we shall form a Leyden arrangement with a dielectric of very low resistance, the liquid taking the place of the glass insulator. Now, if we statically charge this arrangement by connecting the positive and negative poles of a galvanic battery to the platina plates, there will be not only a displacement of the forces, but an actual breaking down and partial reorganization of the atoms composing the dielectric, and an approach to their union with the platina plates.

In this example we have a statical charge, or storage of energy, of a much greater quantity than is possible with a Leyden jar; but as the dielectric is one of very low resistance the potential to which it can be charged is proportionally low. Nevertheless, the storage of energy under such conditions will necessarily be very limited, for, although an actual breaking down and separation of some of the atoms of the dielectric has occurred, the separated electrically charged atoms do not possess sufficient energy to break down the organization of the platina plates, and so form an actual union with them. Consequently they accumulate as a statical charge only, and by their reaction resist the further breaking down of the atoms of the dielectric, but if sheets of oxydized lead be substituted for the platina plates a breaking down and reorganization of the atoms, both of the dielectric and of the lead, will be brought about, and the storage of energy now possible is consequently immensely increased.

What we have seen occurs in a limited degree with platina plates immersed in acid and water when electrically polarized, and what occurs in a very much greater degree in storage batteries explains what electrical energy is striving to bring about in the matter composing a Leyden jar, and helps us to understand the nature of statical charge.

In a storage battery electrical energy produces a very similar condition in the leaden plates to such as we find to exist in fulminating compounds, gunpowder and organic matter, in all of which we have matter and force locked up together, and in a condition of more or less unstable equilibrium.

I have now, step by step, linked together statical charge, electrical polarization, storage batteries, explosive compounds and organic matter, much in the same way as in a previous portion of this article I have indicated the successive links in the chain which connect the action of gravity on matter with the production at the end of the chain of electrical energy; and I would here point out that if there be a difficulty in comprehending the nature

of a statical electrical charge, it is equally difficult to understand how energy can be confined in gunpowder or organic matter, and I would further point out that the energy given out by a storage battery is very different from the energy directly produced from organic matter or explosive compounds, and the only thing they have in common is that when energy is dissipated, whatever be its source, such dissipation always assumes the form of heat.[1]

Electricity and energy are so intimately related, that it seems necessary to say a few words on the subject of energy.

Scientific progress may be said to be directly proportionate to the accuracy of our knowledge of the forces the scientist has to deal with; and great advances can scarcely be expected to be made by microscopically examining scientific phenomena separately, and simply measuring them.

To make important progress, it is necessary to leave the beaten track traveled over again and again by scientific schools, and to seek some elevated standpoint outside where one can look down upon matter and its associated forces as a whole.

If we seek such a standpoint, one of our first observations will probably be that matter and force form a mysterious duality.

There is abundant evidence of force being locked up in matter, but not a single example of force isolated from matter; we may therefore almost safely assume as axioms the following propositions:—

1. As we have evidence of force being confined in matter, and never find it separated from matter, that matter is the home of force.

2. That as force cannot be separated from matter, where there is no matter there can be no force.

3. That as the existence of force involves the existence of matter wherever force is exerted through what is termed space, be it the action of the earth's magnetism on a compass needle, or the radiations from the most distant of the stars, the energy received must have been transmitted through a medium of some sort, and if the above three propositions be admitted, it follows as a corollary that our solar and stellar systems float in an ocean having properties in common with matter; but when the mind tries to grasp what must be the nature of this medium, or ether, as it has been termed, it is confronted with what seems to be an insoluble problem, for it becomes necessary to conceive the existence of imponderable matter, in other words a peculiar kind of matter in which the distinguishing characteristics of matter, viz., weight and inertia, are absent. Mathematicians seem to be able to grasp the conception of such a medium, and Sir W. Thomson has attempted to give a popular illustration of it by means of two illustrations. The first illustration assumes it to have the property of a stiff jelly, which will allow a ball inserted in it to oscillate backwards and forwards, but not to pass through, because the jelly is a solid; the second illustration assumes it to have, in a very refined degree, the properties of pitch which, though brittle and solid, possesses the property of fluidity, and will allow a denser body to pass through. Now although the phenomena of electricity and magnetism not only require for their explanation the assumption of a continuous chain of matter, but seem, also, to demonstrate as clearly as anything can be demonstrated the existence of such a chain, still it is impossible to understand the existence of a medium having positive and negative properties at one and the same time, and therefore I cannot regard the ether theory otherwise than as a sort of Athanasian creed, occupying the place it does in the absence of more complete knowledge.

When force is transmitted by a dynamo driven by a steam engine we have energy unlocked in the fire grate partly transformed in the boiler, and completely transformed in the steam engine, directly to the amount of mechanical force produced and expended in the production of electrical motion in the armature coils and conductor, and also in overcoming the magnetic inertia and maintaining the magnetic polarization of the field magnets. We see, here, there is a series of transformations before the heat energy becomes converted in electrical energy, and the fact of this series of transformations intervening has raised the doubt in my mind, which has been expressed in an earlier portion of this article, whether there is such a thing in a strictly true sense of the term as the conversion of one force into another.

There is a wonderful parallelism and harmony in all the phenomena of nature, and in this comparatively advanced period, everything produced by labor, is in a sense, a form of energy; the production of a picture, or the making, say, of a chair, involves labor, and the picture and the chair are the complement or balance of the energy expended, and which was obtained from the consumption of food; but it can be scarcely said that the picture and the chair have locked up in them any of the forces which were stored up in the food eaten. Now the chairmaker and the artist cannot directly obtain from their respective productions the energy expended in producing them, but through the convenient medium of money they can do so; and in the case of the artist, not only can he obtain stored-up energy to the amount consumed, but he can obtain a great deal more, because he is an advance on ordinary matter and possesses something approaching to creative energy. In an earlier period of the world's history, when trade was carried on by exchange and barter, the invention of money was as great an advance as the determination of the mechanical equivalent of heat in our own day, and the man who invented it was the Joule of his period, as his discovery enabled the multitudinous forms of human labor to be dealt with in terms of energy. The possession of gold gives a man energy of position, which is really the same thing as what we call storage of energy.

In the labor market, 1 lb. of gold may be said to have about thirty times the energy of the same weight of silver, and 1 lb. of silver about 100 times that of copper.

How suggestive this is of the atomic weights of the material elements which vary so much. The atomic weights are, after all, only an expression of the relationship of elementary atoms to electrical and chemical energy stated in terms of their relationship to gravity, and it was the want of harmony here shown between gravity and electrical energy in their action on matter which suggested the doubt whether gravity and electrical force could possibly be protean shapes of a common principle, and which the conversion of one form of energy into another form of energy seems to assume.

I wish now to say a few words in reference to the earth considered as a conductor, for, as shown by the correspondence which crops up from time to time in the *Electrical Review*, as well as electrical literature, the views entertained by some electricians would appear to be somewhat hazy; for example, in Culley's work, the text-book adopted by the postal telegraph department, there is the following passage:—"It was at one time imagined that the earth completed the circuit precisely in the same manner as a return wire; this opinion is now considered incorrect."

When a young man, I made the discovery, or I thought I had, that all true science could be explained by common sense reasoning, and that when a so-called scientific explanation did not harmonize with common sense, then such explanation might be suspected of being unsound. Huxley, who is happy at phrases, has expressed much the same view by describing science as disciplined common sense.

I am of opinion that Huxley's dictum is sometimes overlooked by scientists, and that the extract I have made from the text-book of the postal telegraph department is a case in point. Why should the earth be an exception to other electrical conductors. I think it may be safely asserted that although similar results are often brought about by very different methods, Nature never performs the same operation in more than one way. for example, the various types of dynamos all develop electrical energy in a similar manner, and animals and insects possessing sight see all of them through optical organs resembling one another and acted upon by light in a precisely similar way, and when the earth forms part of an electric circuit why should electricity follow another law in this part of the circuit?

In papers published 30 years since in the transactions of the institution of Civil Engineers and Society of Arts, I described among other things the relationship of the earth to the insulated wire of a telegraph circuit, and also to statical electrical phenomena.

I also described in what way submarine circuits differed from overground ones, and I called attention to what older electricians knew under the name of absorption of charge, which I said might be considered as an approach to conduction. I mention this because it has since been christened electrification, and Fleeming Jenkin credited with the discovery of it.

I pointed out what was scarcely appreciated in those days, that the tension, or as it would now be called the potential of a current, where it entered the insulated wire of a telegraph circuit would be limited by the total resistance of the circuit, and adding to the number of battery cells would not in a circuit (whose resistance was so small as to be a negligible quantity) practically increase the potential, and I stated that the earth owing to its great mass relatively to an insulated telegraph wire might be regarded as a conductor having no resistance, and consequently the potential would be infinitely small and practically the same in every part of this portion of the circuit.

I said that the prime conductor of a frictional machine formed one coating of a Leyden arrangement, the air, the dielectric and the earth the other coating, that the only difference between it and an ordinary Leyden jar was that as the surface of the earth was immensely larger than that of the prime conductor, and as the positive electricity on the one surface was balanced by an exactly equal quantity of negative electricity on the other surface, the potential on the larger surface was less than that on the smaller surface directly as their difference of area, and where as in this case the earth formed one of the coatings, the potential of the electricity accumulated on so extensive a surface was so small as to be inappreciable. I mention this because certain consequences follow from what I then pointed out which I think are not appreciated even at the present time.

In those days it was very generally considered that the transmission of currents through an underground circuit followed an

1. I assume there is no such thing in the strict sense of the term as dissipation of energy; what is termed dissipation of energy is a local dissipation only.

altogether different law from that which governed conduction in suspended circuits. I urged it was impossible to believe that nature had one law for an insulated suspended wire and another one for submerged and underground circuits; and I stated that the only difference between them was one of degree. I further stated that although the accumulation of statical charge in a suspended circuit was, when compared with that of a submerged conductor, so small as to have been generally overlooked; still it was there, and could be seen, that I had obtained very decided indications of it in a suspended wire of 60 miles in length, using an ordinary lineman's galvanometer, and that with more sensitive instruments it could undoubtedly be seen on much smaller lengths.

I pointed out that although a submarine circuit had been considered to be similar to an ordinary Leyden arrangement there was *practically* a very great difference between them. I stated that it was well understood that induction involved insulation, and that where there was no insulation there could be no statical charge, that the insulation separating the inner and outer coatings of a Leyden jar was the resistance of glass, whereas the insulation separating the inner and outer coatings of a submarine circuit considered as a Leyden arrangement was the resistance of the copper conductor only, the inner coating of the Leyden arrangement, and connected through the circuit of the telegraph instrument by a metallic conductor to the outer coating, viz. the salt water of the ocean.

Now this was quite overlooked by our leading scientific men, including Professor W. Thomson, and even Faraday, until after I had pointed out. Snow Harris had stated that induction decreased as the square of the resistance separating two conductors, but I suspected the truth of this law, for the reason that electricity was not a radiant force but a dual one, and that wherever there was free positive electricity, there must be in its neighborhood an equal amount of negative electricity, and this was irrespective of any difference of surface there might be in the two conductors between which the induction occurred, and as a result of series of experiments carried out at the time when I was writing my paper, I found induction followed the same law as conduction, decreasing between flat plates directly as the distance separating them, or, to put it in another way, if a Leyden arrangement, which we will call No. 1, be constructed of two metal plates separated by a dielectric, say $\frac{1}{10}$th of an inch thick, and a second similar arrangement be constructed with a dielectric of $\frac{2}{10}$ths of an inch, No. 1 will have twice the storage capacity of No. 2, or to state it differently, if in No. 1 arrangement 20 units of electricity were necessary to electrically charge the plates to a potential of 10, only 10 units of electricity would be required to raise No. 2 to the same degree of potential.

There is another experiment I tried at this period, and repeated more carefully a few years later. I mounted on a cylinder of annealed soft iron, 6 inches long and ½ inch in diameter, two wooden discs about 6½ inches in diameter. I then wrapped two layers of No. 18 B.W.G. insulated copper wire immediately on the iron core, counting the number of convolutions; after this I wrapped the bobbin with string to a diameter of 6 inches, and outside the string I wrapped two layers of the No. 18 wire, counting the number of turns, so as to be sure there was the same number of convolutions in each set. The length of the insulated wire of the outer convolutions was approximately 12 times that of the convolutions of smaller diameter; and the mean distance of the outer convolutions from the centre of the iron core was approximately 12 times that of those wrapped immediately upon it.

I joined the convolutions of insulated wire in series, but so connected them that the electricity circulated when the battery circuit was closed in opposite directions through the two sets, and I found when I closed the circuit, there was not the slightest trace of magnetism produced, thus showing that an electric current flowing through a circuit whose length was 12 and whose distance from the centre of the iron core was 12, had the same magnetizing influence as a conductor whose length was 1 and whose distance from the centre of the iron core was 1 also.

I wish now to point out certain consequences arising out of these experiments, but these must be deferred to the continuation of this article in next week's *Review*.

(*To be continued.*)

.... DOGMAS have their use undoubtedly, and the phrase, " heat is a mode of motion," shines with a reflected glory, simply because some of our most eminent scientists have been content to accept the dogma as a rallying point or flag; and it is the work they have accomplished fighting under this banner, and this work *only*, which has given a value to the phrase, much in the same way as that given to the tattered rag some distinguished regiment carries into battle, and around which men fight and die, and which in the end finds deservedly a resting place in our cathedrals, because it symbolizes that which distinguishes men among men, and man as man from the greater part of creation.—*S. A. Varley.*

ABSTRACTS AND EXTRACTS.

BLOCK SIGNALS.

THE following letter on Block Signals on American Railroads, appeared in the *Railroad Gazette*, for August 24. We append the editorial comments from the same number of that journal.

To the Editor of the Railroad Gazette:—

The expense incurred by railroads operated under the block system would naturally lead to the conclusion that it was an additional safeguard against accident. But with an experience of more than 10 years in train service as freight and passenger brakeman and conductor on roads so operated, I claim that the facts do not sustain the theory. I have yet to learn how the system will prevent an accident, while, on the contrary, I can recall many instances when it has been the cause, indirectly if you choose, of rear end collisions. Advocates of the system will claim that it is owing to neglect of positive orders by the trainmen that makes a rear collision possible. That I concede, and it is my objection to the system that it will make the most careful flagmen and conductors careless. It offers a premium on negligence. It makes trainmen negligent in the discharge of positive orders, less sensitive to danger and the necessity of protecting themselves against following trains. The responsibility of protection is, in the face of positive orders to the contrary, divided between the train crew and the operator, or block. Trainmen do and will rely on it for protection, any rules to the contrary notwithstanding. If two trains were not permitted on the same block, and no clearance orders given contrary to the indications of the semaphore; and if enginemen of following trains were informed that they must rely solely upon the block, as no flagman from the preceding train would be sent back to protect it, the system would accomplish the result intended.

Observe the movement of the rear brakeman on the Central of New Jersey when his train slows up to make an unusual stop. If he is where he has not an unobstructed view in the rear of his train, he is off, and back with a flag before his train comes to a stand still. Do you note the same vigilance on a road operated under the block system? My experience is that the brakeman there usually wants to find out what the trouble is; wonders how long they will be detained, and if he goes back at all, it is a very short distance, and then only after the train has stood 5 or 10 minutes. Running close behind him is an extra train, or a delayed passenger train, anxious to make up as much lost time as possible. The engineman arrives at A, is stopped by the block and informed that train No. — has not cleared B at the time he receives his order; that he may go on, but must run cautiously. But away he goes at schedule speed if not faster. He is behind time, he has the opportunity, and desires to make a good run—all enginemen do. The passengers demand it, and the officials require it of him. He reasons that he is perfectly safe in maintaining a high rate of speed, because if the preceding train has not cleared B it will have a flag out far enough behind to stop him. That is where the system invites disaster. If he knew that no flagman would be sent out from the train ahead he would not hit it. He would " run and look," prepared to stop within a train length where the view ahead was obstructed.

The most extensive system operated under the block did not have a rear collision during the Centennial in 1876, and its passenger business was enormous. It placed on its passenger trains its most reliable freight conductors and brakemen, and it was due to their vigilance, and not to the block (which was then a new thing there), that they were so free from accident. Just at the close of the heavy traffic, a local train in charge of conductor Thomas Gallagher, ran into a freight at Linden, and a few days afterward he ran into another freight that was pulling into a siding at Menlo Park. Both accidents were indirectly caused by the block system.

Quite recently I went into the office at A and reported my train clear of main track on a siding, half a mile south of the station. The operator looked at his train-sheet and replied: "I have you reported clear at B, at —, " stating time. I had not been south of switch when my train was side-tracked, and B was four miles beyond it.

I have asked hundreds of railroad men their opinion of the system, and I have yet to hear the first conductor, engineer, despatcher, or any man directly connected with train service, say a word in its favor.

LANGDON.

[EDITORIAL.—*Railroad Gazette.*]

WE print in another column a letter from a trainman concerning the practice of some American roads in block signaling. We publish this letter because it is not merely the opinion of a freight conductor, but is also a good representation of the views held by many intelligent superintendents. Notwithstanding the widespread use of, and faith in, the principles of block signaling, there is a strong sentiment in various quarters that there are good arguments on the other side. These arguments are not often formulated, but the feeling exists, nevertheless. This letter constitutes a strong expression of what may be called the Jersey Central senti-

ment; the conviction that, with wide-awake trainmen, fully alert to their duties, train running can be carried on better without block signals than with.

The primary object of block signaling is often lost sight of. It is not to be denied that in clear weather, by daylight, and with young and lively men, trains can be run on thousands of miles of railroad, for scores of years to come, with substantial safety and without block signals. But the very first reason for adopting block signals years ago, and the most important reason demanding their adoption now, is the fact that trains must be run when the weather is not clear, when the darkness is thick enough to be felt, through tunnels full of smoke and with men who will sometimes be negligent. Every one recognizes that under certain conditions, traffic will be more or less delayed by the use of the block system. Last year's collision at Hexthorpe, England, where 19 people were killed, is a melancholy illustration of the strong influence which this idea exercises over the minds of otherwise cautious railroad men. An immense traffic was imperiled and was actually involved in disaster because the delays necessary for safety were deemed unendurable. The theory of men like our correspondent doubtless is that the block system may be useful at night and during stormy weather, but that we should work without it when the weather and other conditions are favorable. But by a moment's reflection we see that any such partial or intermittent use of the system will bring in more dangers than it will cure. If we are to have the benefit of the principle at any time, we should employ it systematically at all times, and put up with the incidental inconveniences. Conditions of this kind have to be submitted to in other departments of business and are recognized as based on just principles. Book-keepers every day make hundreds of figures which would be unnecessary, and a waste of time, except for the necessity of following an inflexible system. "Langdon's" way of running trains recognizes this principle by making strict rules about going back with a flag when the brakeman is morally certain that no train is following.

The use of permissive blocking, which is the basis of the illogical system complained of by "Langdon," and which is quite prevalent in England as well as in this country, cannot be regarded otherwise than as an evil. It may be admissible as a lesser evil, but it should be clearly understood that its faults are not chargeable against a scientific block system. It brings in just the train of doubtful conditions described in this letter, and neutralizes much of the good effect of an otherwise almost perfect system. The reason why "Langdon's" experience of 10 years and the opinions of the hundred men he has talked with are against the system is found in the existence of this loophole. Telling an engineman to run cautiously, and telling a flagman to go back with red signals when he knows that his going back will almost certainly be unnecessary, constitute one of the most troublesome combinations in railroad practice. The absolute block system in perfection entirely obviates "going back to flag." The old plan makes flagging of vital importance. Permissive blocking mixes the two, and while perhaps preventing some rear collisions, certainly leaves the door open for one large class, those which occur from careless handling of trains when it is known that other trains are near. The essence of permissive blocking is to run with caution; but most rear collisions occur when the runner is using some caution, not when he is "humming along" at full speed. Railroad men who argue against the block system are prone to pass lightly over the objections brought against *their* system as regards its suitability for a heavy traffic where tunnels are numerous, fogs frequent and night trains heavy. But passengers now-a-days want to ride as promptly, as fast and as safely when the engineer can not see the chimney of his own engine, as when he can see three miles ahead.

The statement that officers demand fast running by engineers when it is not safe to run fast, is undoubtedly practically true in many cases. As in the case of men sent out with money to influence a legislature, the injunction is to do nothing wrong, but the person enjoined unmistakably understands that he must achieve success. The mistake of an operator which has recently come under "Langdon's" observation shows the value of electric locking for block signals.

PROTECTION FROM LIGHTNING.[1]

THE present season of thunderstorms brings the question of protection from lightning into special prominence. It is a matter in which every one is interested, for the electric fluid is no respecter of persons, and strikes both at the hut and the palace, while it does not always spare the lonely wayfarer plodding along the road far from buildings of all kinds. It is, however, high and isolated edifices that suffer from it most; churches, factories, farm-houses and country mansions are specially liable to its attacks. There are, however, now very few of these not furnished with conductors which are presumed to afford complete protection. Usually they do, but still it is by no means uncommon to hear of the lightning leaving a stout conductor to play vagaries within the building, springing hither and thither, and leaving most unpleasant footmarks wherever it alights. Until very recently it was customary to assume that the lightning conductor was in fault when such an unexpected result was realized. Either the joints were bad or the "earth" was deficient. Among rods of early date the latter was very often true, for they sometimes penetrated but a very short distance into the soil, or ended in a stratum which became perfectly dry during the hot months of summer. But when every allowance has been made for such imperfections in construction and erection, there still remain many cases of failure which are not easy to explain without recourse to researches which have been made public during the last few years, and which tend to weaken our faith in the theories regarding protection from lightning which were current only a very short time ago. When electric self-induction began to be studied by practical men, it was seen that it must have a great bearing on the conditions under which a flash of lightning can pass along a conductor. The question of a more or less perfect earth loses much of its importance in the face of a counter electromotive force of thousands of volts suddenly generated in the rod, and opposing the quiet passage of the lightning. It only lasts the minutest fraction of a second, but then lightning cannot brook any delay, and it will strike out from the rod in gushes at any place where a neighboring conductor offers it an alternative path, often traversing a foot or two of air, or piercing a brick wall in its attempt to escape. For purposes of analogy we may compare the effect of self-induction to that of inertia, to which it bears a great similarity. The rod is full of quiescent electricity, when suddenly the lightning starts from the clouds, and with one mad spring through half a mile of sky, it enters the conductor, seeking to rush through it to the ground. But to do this it must set in motion the electricity with which the rod is already filled. The effect is like a piston coming down on a mass of water in a steam cylinder; an enormous pressure is set up, and the fluid seeks every avenue of escape, spurting through joints and stuffing-box, and sometimes carrying the solid iron of the cylinder cover with it. In the same way the electricity will often dart out from the rod, even though the lower end may make most excellent contact with the soil. The self-induction in the conductor is too great to permit of the electromotive force of the discharge falling immediately to a safe limit; it is, no doubt, immensely decreased, for after a flash has traversed half a mile of sky a few feet of air is but a small matter.

The difficulty of getting an electric discharge to traverse a metallic conductor has been demonstrated by Dr. Oliver Lodge in a very simple but convincing manner. He takes two Leyden jars and connects their inner coats respectively to the two terminals of a Voss machine. Between the outer coats there are practically three paths along which electricity can travel, namely, the table on which they stand, an adjustable air gap between a pair of discharging balls, and an insulated wire. The table forms an imperfect conductor between the jars and the ground, while the insulated wire guarantees that the jars shall remain at the same potential. There are also a pair of adjustable discharging rods between the terminals of the machine. Now, when the machine is worked the electricity accumulates in the jars, and while it is doing so the outer coatings remain at the same potential, there being no current in the wire connecting them, and no tendency to spark at the air gap. The tension in the jars, however, rises until it is able to leap across the space between the terminals of the machine, whereupon there is an instant rush of electricity between the outer coatings. There is practically no path for it along the table, and hence, it must go along the conductor, or across the air gap, or by both paths. Now, as the resistance of air is millions of times greater than that of metal, we might, at first sight, assume that there could be no spark between the terminals. But Dr. Lodge shows that when the conductor consists of 40 ft. of No. 1 (B. W. G.) copper wire, the discharge will as easily leap across a space of 14.3 tenths of an inch as take the easy path open to it. The effect of the self-induction is to raise the natural resistance of the wire from .025 ohms to something which is comparable with 1½ in. of air. If the copper wire be replaced by a similar length of thin iron wire (No. 27) having a resistance of 33.3 ohms, a still more unexpected result is obtained. The resistance of the metallic circuit is now 1,300 times as great as before, but instead of the discharge being able to leap a wider gap it can only bridge 10.8 tenths of an inch of air. If the continuous circuit be made through a capillary tube of liquid having a resistance of some 300,000 ohms, the spark length increases to 16 or 17 tenths.

We do not, however, need to employ even the very simple apparatus described above to demonstrate the tendency of an electric discharge to flash out sideways. If we take a yard of the thinnest platinum wire obtainable, and place it parallel to a thick copper rod, the ends of the wire being bent towards the rod until they approach it within a sixteenth of an inch, then, when the discharge from a Leyden jar is sent through the rod, it will be found that a part will leave it for the attenuated parallel path, leaping the air gap to reach it. The publication of Dr. Lodge's experiments has drawn attention to certain researches upon lightning discharges for protecting telegraph instruments carried

1. *Engineering* (London).

out in 1864 by Professors Hughes and Guillemin. The results of the earlier trials are in substantial agreement with those of the later ones, except as regards the superiority of iron over copper as a conductor. It was found that no discharger would protect the coils of the instruments if a very powerful discharge from a large battery of Leyden jars was sent through it, and that if the discharger were replaced by a copper rod of 1 centimeter in diameter, sufficient electricity passed by way of the instruments to burn a fine iron wire. When, however, the wire was replaced by a flat plate, even of tinfoil, a very large measure of protection was obtained. We thus see that ordinary measurements of resistance applied to lightning conductors may be very misleading if other conditions are not taken into consideration.

When the existence and the effects of self-induction are appreciated it is easy to point out the means to minimize the latter. Clerk-Maxwell showed that "the electromotive force arising from the induction of a current on itself is different in different parts of the section of the wire, being in general a function of the distance from the axis of the wire as well as time." Professor Hughes has also experimentally investigated the comparative effect of disposing the metal of a conductor in different ways. He found that self-induction is reduced 80 per cent. in iron and 35 per cent. in copper by using the metal in the form of a flat strip or ribbon instead of in a cylindrical wire, and that if the ribbon were divided longitudinally into bands, and these were placed a little distance apart, the self-induction was still further reduced. He therefore recommended the use of copper strips for lightning rods. Dr. Lodge has also pursued the same line of investigations, using, however, the discharge from a Leyden jar, as more nearly resembling lightning than the interrupted currents of Professor Hughes. He proved, using the apparatus referred to above, that if a copper wire of given weight and length were employed to connect the jars, then when the air gap measured 8.86 millimeters the discharge would sometimes take place by the wire and sometimes through the air. If a ribbon conductor of the same weight and length were substituted for the wire then the air gap must be reduced to 6.25 millimeters before the same conditions were attained, thus showing that the ribbon presented an easier path for the discharge than the wire, although the metallic resistance of the two was equal. Dr. Lodge's experiments also seem to show that iron is quite as advantageous as copper as a material for lightning conductors, and he goes as far as to say that he considers the use of copper as doomed. It is well known that iron has far more self-induction than copper when tested in the ordinary way, and hence it offers a greater "impedance" to the passage of a current than the other metal. But when the discharge from a Leyden jar is substituted for the interrupted current then a result is obtained which suggests the explanation that the magnetic qualities of iron have not time to come into play during the passage of the discharge.

Now in what way are the experimental data we have mentioned to be applied in practice? Shall we abandon our accustomed plan of seeing that the joints of the conductor are well and securely made, and cease to care whether the "earth" offers a great resistance or not? He would be a bold man, we think, who would venture to do this. The utility of the old plan has been proved in so many thousands of instances that it would be most foolish to abandon it on the strength of laboratory experiments. A Leyden jar is not a thunder cloud, and it is quite possible that its discharge does not exactly simulate the effects of lightning. But it would be equally unwise to neglect the latest teaching of science, for although lightning conductors generally serve the purpose for which they are designed, there is still a long list of unexplained failures which disturbs our faith in their efficiency. The safe course seems to be to graft the new principles on the old practice. Let us abandon the old cylindrical rod for the flat tape, or, better still, for a number of tapes or small wires led down different parts of the building, so that they may be beyond the sphere of each other's influence. Another point of importance is to provide plenty of electrostatic capacity for the reception of the flash, and thus to keep the electric tension moderate. Professors Hughes and Guillemin found that if they substituted a large condenser for their lightning discharger the result was far better. A splendid example of the protective power of an extensive metallic surface came to light in 1873, when the conductors of St. Paul's Cathedral were overhauled. It was found that the original conductors which had been erected for the protection of the dome had been cut through in the course of some alterations, and partly removed. The lead covering was absolutely insulated from the ground, and had been for some years. During that time it is certain that it must have been the recipient of many lightning flashes, yet it had never suffered any injury. It had taken them all in like the coating of a Leyden jar receives the output of a machine, and had held them until they leaked away down the wetted stonework, and thus gradually got away to earth. Unfortunately, leaden roofs are not very common in modern buildings, but where they exist they should be connected to the conductor at several points. This latter precaution is to avoid the destructive effects of the surging of the electricity which seems to take place after a flash, and it is of great importance. We have not, however, the space to enlarge on that point at present, but shall probably return to it in an early issue. For the present we must confine ourselves to the points mentioned above, with the addition of a caution against undue elevation of the point of a conductor. A lightning flash is too dangerous a visitor to be invited. Ample preparations must be made for its reception; but still its visit is not desirable, however hurried it may be.

VON HEFNER ALTENECK'S AMYL ACETATE STANDARD OF LIGHT.

The author has investigated the effects of changing the dimensions of various parts of the lamp from the normal values as settled by the inventor. An important point in the constancy of the standard is the height of the flame; and the following table shows the results obtained by altering the height from the normal height of forty millimeters:—

Height of flame.	*Illuminating power. Standard candles.*
20 mm.	0.38
25 "	0.55
30 "	0.70
35 "	0.85
40 "	1.00
45 "	1.12
50 "	1.25
60 "	1 50

Increasing or decreasing the diameter of the wick tube by two millimeters at a time diminishes the light by one per cent.; so that the dimensions chosen by Von Hefner Alteneck gave the maximum of light. An alteration of the portion of the wick tube which rises above the body of the lamp by one millimeter, makes a difference of 0.2 per cent. in the light.

In the old form of the amyl acetate lamp the height of the flame is gauged by a sight carried on the top of a small rod fitting into the body of the lamp. Dr. Liebenthal has introduced an improvement on this arrangement. The lamp is provided on one side with a vertical screen, the upper edge of which carries a small camera; the lens is turned towards the flame, and has such a focal length that the image of the tip of the flame is seen clearly on the disc of white alabaster glass which forms the back of the camera; by means of a scale on the glass the exact height of the tip of the flame can be read in millimeters, the middle division corresponding to forty millimeters.—*Elektro-technische Zeitschrift.*

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Board of Electrical Control.—Dangers of the Elevated Railroad.—Electric Traction on Fourth Avenue.—Rival "Ticker" Interests in Court.—The Telegraphers' Mutual Benefit Association.—Lecture by Dr. Wheeler on Electricity.—Opening Meeting of the American Institute of Electrical Engineers.

Recent meetings of the board of electrical control, indicate that the proper regulation of the overhead lines is becoming a matter of apparently more importance than the question of placing them immediately underground, which is now generally understood to be a work of considerable magnitude. There have been a good many permits issued for the erection of new poles in order that contracts for the lighting of streets could be carried out. Under one of these, the Mount Morris company has constructed a new line from Harlem to Washington Market. None of the arc lighting lines in the city are, however, up to the standard which will warrant the board in granting certificates of inspection as required by the rule adopted July 2d, which is for the time being inoperative. At the meeting of September 18th, a new rule was adopted upon recommendation of Dr. Wheeler, fixing the height of out-door lamps at nine feet and in-door lamps at eight feet. A small sample of underground conductor was presented to the board for approval which was to be placed in the Sixth avenue conduit by the East River Electric Light Co. It was decided that it was not within the province of the board to determine in advance whether such a a conductor was suitable, but that it was the duty of the manufacturer to ascertain the requirements and govern themselves accordingly. The electrical expert would make the necessary tests after the conductors were placed in position and if they did not come up to the standard they must be removed at the expense of the contractor, and consequently electrical companies should see that they were protected against the possibility of inferior insulation in their agreement with the manufacturer. The inspection of overhead lines has now been going on for over two months and about 15 per cent. of the defects reported have been remedied, but it will be some time before the lines are in good condition on account of the great extent of territory which they cover. An electric light wire fell across 28th

street, one rainy night last week, and a passing cab horse stepped on it and was thrown down. No damage was caused however.

It would not be out of the way, if a board of control was appointed to look after the dangers of the overhead railroads as well. An iron shoe, weighing 14 pounds, fell from one of the trains in the Bowery near Grand street, a few nights ago and scraped the person of Steve Brodie sufficiently close to tear his trousers. It was a narrow escape, and he was not injured in the least.

The beginning of regular trips by the new electric motor cars on the Fourth avenue railroad is considered quite an important event in the march of improvment. These cars are operated by the Julien storage battery, and they have been built expressly for this service. The most radical departure in the construction of the car itself is the use of double trucks. It is to be hoped that their operation will be sufficiently successful to lead to a reconsideration of the determination of the Third avenue people to introduce the cable system on that line.

The Kiernan News Co. has been again in court. This time an attempt was made to secure a continuation of the injunction against the Stock Quotation Co. for purloining news from the tape of the Kiernan "ticker." The evidence was secured in the usual manner of fabricating bogus despatches which were at once copied, so it was claimed by the rival concern. Judge Barrett, of the Supreme Court, refused to grant the motion because the evidence was conflicting. It is said that the Stock Quotation Co. was about to bring a similar suit against Kiernan.

The annual meeting of the Telegraphers' Mutual Benefit Association, will be held in this city, at the Western Union building, on Wednesday, November 21st. There are several proposed amendments to the constitution and by-laws to be acted upon, among them being a proposition to add a medical director to the board of officers, whose duties will be to pass upon all applications for membership. Medical examinations have been insisted upon heretofore, but the examiner was not a regular officer of the association as is now contemplated. This association is now one of the oldest and most important of its class, and its statistics are therefore of great value for the guidance of other organizations. It has already passed through one serious epidemic of yellow fever successfully, and will no doubt succeed in doing so again as its surplus is ample to guard against any probable loss which would impair its stability.

The Young Men's Christian Association has arranged a very interesting series of "Practical Talks by Practical Man," for the month of October. The first will occur on Friday, October 5th, when Dr. Schuyler S. Wheeler, of the Board of Electrical Control will talk about the modern applications of electricity. He will be assisted by Mr. Francis B. Crocker, and the lecture will be copiously illustrated.

The American Institute of Electrical Engineers, will hold the first meeting of the season on October 9th, when Mr. Frank J. Sprague's paper on "Municipal Rapid Transit" will be discussed. The paper was read June 19th, and published in the August number of the ELECTRICAL ENGINEER. On account of its length and the importance of the subject it was deemed proper to defer the discussion until the opening of the next season. Those who are not members of the Institute but desire to be present, may obtain admission cards by addressing the secretary, Ralph W. Pope, No. 5 Beekman street, New York.

The position taken by the United States Illuminating Co. with regard to subways has brought about considerable feeling between that company and the Board of Electrical Control. Upon the 21st of September some workmen, employed by the Bureau of Encumbrances, engaged in removing a line of poles along Sixth avenue, found it necessary, in order to remove the pole at the southwest corner of Sixth avenue and Thirty-sixth street, to cut one of the circuits belonging to the United States Illuminating Co., which supplies current for nearly 50 arc lights for private use. An inspector of the United States Illuminating Co. consented to cut the wire, upon the express understanding, so he states, that they be allowed to connect the wires as before, as soon as the pole was removed.

The wire was cut and the pole removed, and then the linemen of the electric light company attempted to join the severed wire. Here, it is claimed, the subway commissioners, through their subordinates, stepped in and forbade the proceeding, urging that, under existing law, no electric lighting company could, under any circumstances, repair or alter old or stretch new wires on poles in this city. Their employés could only climb the poles for the purpose of taking down the wires and placing them underground.

A policeman was stationed upon guard to prevent any interference with the wires. The various patrons along Broadway and Sixth avenue, to the number of fifty, are deprived of electric lights, much to their indignation.

President Lynch thus concludes his version of the affair: —

"Now, whatever the rights of the Board of Electrical Control in this particular case may eventually prove to be, Friday's proceeding was, to say the least, a breach of good faith on its part, and an exhibition of petty annoyance unworthy and undignified on the part of any body claiming to derive its authority from the State of New York."

On the other hand, the subway commissioners claim that the electric lighting concern cut its wire at the request of the Bureau of Encumbrances and not at their instance. President Hess said that subways had been provided for the carrying of all electric wires underground, and that the United States Illuminating Co. was the only concern of the kind that refused to obey orders to bury its wires. Secretary Morse declared that had Mayor Hewitt given the subway commissioners proper support there would not be a wire above ground up-town.

NEW YORK, September 28, 1888.

PHILADELPHIA.

The Meter to be Used by the Edison Company in Philadelphia.—Camden Streets may be left in Darkness.—The Gas Company Obstructing Electric Lighting.—Trouble over the Tearing up of Sidewalks by the Telephone Co.—The Thomson-Houston Company demands Royalty from the Electric Light Co., at Carlisle, Pa., on its Regulator Patent.

THE use of meters in electric lighting is comparatively new to Philadelphia. "We will introduce the meter here when we get our new station on Sansom street in operation," said Mr. Kepler, one of the agents for the Edison system, recently. "It is what is called a weight meter, and works perfectly. It will be used in all establishments where we furnish the lighting, and will show just how much electricity is used. Such a thing is absolutely necessary for our protection, for people are apt to be extravagant in the use of electric lights and let them burn much more than they would gas, as they give out no heat and cause no inconvenience in any way. If we were to make contracts to supply just so many lights to storekeepers and others we could not tell how much electricity would be used, but you may be sure that the lights would be burned much more than there was any necessity for.

"The accuracy of the meters is shown by the fact that the Edison company has about 1,800 customers in New York city, and only one of them has been dissatisfied with the readings of the meter. Drexel, Morgan & Co. kept a private record for months of the length of time their lights burned, and the amount of electricity used, as estimated by their figures, varied only three per cent. from the statement in the bill of the Edison company, and the difference was in favor of the meter."

The possibility of darkness for an uncertain length of time in all but five streets stares Camden, N. J. (across the Delaware from Philadelphia) in the face. The gas company maintains a defiant attitude and refuses to sign a contract to furnish gas for the street lamps unless the lighting committee of city council shall restrict the number of electric lamps to 36. The gas company's old contract expired on July 1, but it has since been supplying the city under its provision until a new contract can be awarded.

The members of the city council lighting committee, it seems, have an idea that they were elected to serve the people, and take tight hold of the horns of the dilemma.

City-solicitor J. Willard Morgan had drafted the contracts for the two lighting companies, and had them ready for the signatures of the proper officers, and when the committee met at the City Hall, the documents were yet unsigned. A number of citizens had gathered to watch the proceedings, and they took a great deal of interest in what transpired. The solicitor read the long documents, while the members of the committee listened attentively. At the conclusion of the reading there was a spell of deep silence. Then it was stated that the gas company representatives objected to signing the contract prepared for them because there was in it no stipulation that the number of electric lights should be restricted to 36, as that was the number decided upon by the committee, and there would be no money in the contract for the company at its bid of $25 per year for each gas lamp if the number of electric lights should be increased beyond 36.

"I know of nothing in the records of the committee of council," said chairman Dorell, "showing that the number of electric lights was to be restricted to 36. The chair will entertain a motion to approve the contracts as drawn by the solicitor."

Mr. Roberts then, with a little amendment tacked on by Mr. Rex, moved that the committee approve the contract as being in accordance with the committee's report on the matter submitted to and approved by the last meeting of city council. The motion was adopted without a dissenting voice, and Mr. Roberts immediately broke in with a motion to place arc lights at five other street crossings not lighted at present. This was followed by a motion of chairman Dorell for six lamps on Broadway, below Kaighn avenue, and Mr. Stone for three lights on Mount Vernon street below Sixth—and all were passed. These additions will make 50 lights in all in the city, and there is a disposition on the part of the committee to still further increase the number, as the aggregate cost is no greater than for gas. After the committee adjourned chairman Dorell and superintendent Mullen, of the electric company, made a tour of the streets to designate the gas lamps to be extinguished. If the gas company should, in the meantime, endeavor to strengthen its position by refusing to light the lamps the city will be in a predicament.

"A high-handed outrage," is what the residents and property-owners on Cherry street, between Third and Fourth, term the recent action on the part of the Bell telephone company in tearing up the sidewalk to lay wires under the street. The business men are in a state of indignation. A gang of 50 men, armed with picks and shovels, marched up to the place and began ripping up the sidewalk right and left. In less than half an hour the sidewalk, from No. 300 to No. 317, had been torn up. Hewey Eaton, whose place of business is at No. 307, remonstrated against the proceeding, but the foreman would give him no satisfaction. He hurried off to consult his lawyer and secure an injunction, but when he returned the pipes containing the wires had been laid and the sidewalk replaced. The telephone company is said to hold a permit for the work from director Wagner and chief McDonald, of the Highway Department, but it is doubted if it was intended they should use the sidewalk. The men whose sidewalks have been torn up are desirous of excavating the ground under the pavements for various purposes, but the laying of the wires will interfere with this work.

Counselor Moore says that the telephone company is liable for damages through its action, and that it did not consult the proper authorities regarding the permit for the work.

Three months ago, Carlisle, Pa., was first illuminated by electric lights by the American electric light system. The dynamos used have automatic regulators.

The Thomson-Houston Electric Co., claim under the recent decision at Boston—that the Carlisle company infringes their regulator patent, and if a royalty is not paid, a suit for damages will be instituted against the Carlisle Electric Light Co. The latter company, however, have retained $5,000 of the purchase money of the plant, and this sum will more than cover the amount of damages claimed by the Thomson-Houston company.

PHILADELPHIA, September 17, 1888.

BOSTON.

The Boston Fire Department and its Work for the Past Year.—Output of Telephones by the American Bell Co.—The Attempt to Regulate Telephone Charges Postponed by Common Council.—The American Bell Telephone Co. to Erect an Office Building.—The West End Railway Co. before the Boston Aldermen.—Hearing on their Petition for leave to Construct Overhead and Conduit Lines for Electric Cars.—Remonstrance against Overhead Wires.

THE work of the Boston fire department for the last year is of much interest. The figures given tell a story of steady progress in the fire-alarm department. Considerable advance has been made in substituting keyless doors for the old kind, and in time they will be in use in all parts of the city. During the severe storms of last winter, which proved so damaging to various branches of electrical service, the fire-alarm wires suffered but little, and no troubles were experienced that a few hours work did not remedy. The system is well in hand, and great care has been exercised to prevent the department from being left helpless in case of possible emergencies.

The city is divided into 10 fire districts. Every box in the city now gives its signals automatically to all the department houses where the box gongs are located. The box gong service has been still further extended and improved by the introduction and use of registers, placed in connection with the box gongs and operated by them, by which a record is made on a paper tape of all alarms received. There are 65 telephones in use by the department at the present time.

A general reconstruction of the wires running to Charlestown and East Boston, has been made, beginning at the Fitchburg depot, and continuing along the route of the bridges, ending at Meridian street.

The poles on Warren bridge have been abandoned, and a 19-wired cable, 1,000 feet in length, has been laid in a conduit across the same.

A sub-marine cable has also been placed at the draw of this bridge, and another at Meridian street.

Thirty-nine new signal boxes have been added to the service during the year.

Two new switch-boards, of elegant design and construction, have been provided for telephone service. They are mounted on black walnut desks which were made for the purpose, and are in use, one at headquarters and the other in the office of the chief engineer.

The usual incidental work of repairs and improvement in construction has been carried on at various points, embracing the renewal of old wire wherever required, and the extension of circuits to connect with new boxes and department apparatus.

Material has been used as follows :—42 miles No. 9 iron wire ; 5½ miles No. 12 copper wire ; 5,800 feet kerite wire ; 220 pounds cotton insulated wire ; 6,500 feet lumber ; 2,050 glass insulators ; 1,500 insulator bolts ; 1,200 lag screws ; 50 poles.

The following are the statistics relating to alarms and fires ; during the year there were 975 alarms in a population of 362,000.

Total number of actual fires	820
Confined to one building	669
Extended to others	25
Wharves, vessels, grass, etc	126
BUILDINGS.	
Slightly damaged	501
Considerably damaged	81
Totally destroyed	31
Not damaged	124

Electric light wires are charged with causing 9 fires ; kerosene in lamps and stoves runs up a bill of 78 fires ; gas and its uses caused 22 fires. The commissioners deplore the fact that the city is "provincial and unachronistic" in having a combination of permanent "call" men.

Nearly 20 call men, 57 years of age, or over, have been retired, and also several permanent men, the latter having served over 15 years in the permanent service, receiving pensions equal to one-third the salaries which they received at retirement.

All of the public clocks, 37 in number, are taken care of by the fire department.

A constant watch is kept at the headquarters, City Hall, night and day, by the operators. Each operator has assigned to him certain hours of duty, during which time he is responsible for the correct working of the apparatus in giving alarms, and all testing of the circuits and other details pertaining to the service. An automatic arrangement is connected with the receiving apparatus, by which assistance may be called from the sleeping apartments, if at any time the operator should be suddenly incapacitated by illness from performing his duties. No operator is permitted to sleep during his watch, unless expressly relieved by some one else, and by consent of the superintendent.

Each operator is accountable to the superintendent for any mistakes that may occur at the office during his hours of duty.

An accurate account is kept of the time of giving each alarm, and of the station from which it originates, and all other necessary information.

There are 400 fire-alarm boxes, divided as follows, viz.:—

Boston	122
South Boston	40
East Boston	33
Roxbury	59
Dorchester	52
Charlestown	37
West Roxbury	32
Brighton	24
Chelsea	1
	400

Thirty-seven of the boxes are private property.

The statement of the output of telephones by the American Bell company for the month ended August 20, and the fiscal year to date is as follows :—

Increase.	1888.	1887.	Increase.
Gross output	3,694	3,533	161
Instruments returned	1,760	3,353	*1,593
Net output	1,934	180	1,754
Dec. 21 to Aug. 20—			
Gross output	37,740	36,541	1,199
Instruments returned	14,646	17,663	*3,017
Net output	23,094	18,878	4,216

*Decrease.

At a meeting of the common councilmen on the 12th, an order was offered for the appointment of a joint special committee, to consist of five members of the common council, with such as the board of aldermen may join, to investigate the question of telephone charges. A motion to indefinitely postpone prevailed by a vote of 40 yeas to 18 nays.

The matters in court, in which the American Bell Telephone Co. is concerned just at present, are: the appeal from Judge Colt's decision, given in Boston (relative to the power of the attorney-general to bring suit to annul the Bell patent) to be heard in Washington, October 11, next ;—and the hearing for preliminary injunction against the Cushman Telephone and Service Co., October 4, next, at Chicago. The Bell company now have a restraining order from Judge Blodgett, restraining the Cushman company from commencing any new telephone business, until the decision on the injunction suit is rendered—which ties them up securely. It was their intention to sell out to a new company against whom the restraining order had not been issued, but this too was prevented by the same order.

The American Bell company have purchased a large lot of land on the southeast corner of Milk and Oliver streets, and their architect, Mr. Fehmer, is now preparing the plans for a fine building, every modern improvement will be introduced, and the building will be worthy of the great business to be housed in it. It is expected that the Boston exchange of the New England Telephone Co. will be removed to the new building, and a large conduit from the street is arranged for to admit cables. The distance from the present quarters is but one block, in an easterly direction.

At a meeting of the board of aldermen on the 28th ult., the matter of electric tramways came up.

The fact that a hearing was to be given on the petition of the West End Railroad for leave to introduce an electric system attracted a large number who are never seen at meetings of the board except on extraordinary occasions, and there was considerable opposition to the project. Mr. Henry D. Hyde, on behalf of the company, explained the systems, overhead and conduit, that it is proposed to use, and said that no new locations are asked for. The poles are to be erected on each side of the street, 250 feet apart. The company has been granted the right for overhead wires in Brookline, and now asks for a continuation of that system down Beacon street, West Chester Park and Boylston street to Hereford street at the new bridge, where the conduit system will begin.

Mr. Waldo Adams, owning property on Boylston street, objected to any overhead system as likely to decrease by its wires the value of that property. He would not object to a conduit system.

Councilman Frank Morison, representing Charles F. Adams, Hollis Hunnewell and other property owners on the Back Bay, objected to an overhead system as likely to disfigure the handsomest streets in the city, to say nothing of the danger to horses and pedestrians from the breaking of uninsulated wires. He thought an electric railway a good thing, but that a conduit system is the only way to run it in the city proper. He thought, further, that now is the time to make a stand against overhead wires.

Mr. Louis Curtis, an owner of property on Beacon street, objected on the same grounds as Mr. Morison. Colonel Henry Lee also opposed the mode of introducing the system, and thought wires should not come farther into the city than the forks of the roads on Beacon street. He thought the posts and wires would be an eyesore as well as a source of danger.

Messrs. F. V. Parker, Gamaliel Bradford, and others, also remonstrated, and then Mr. Samuel Hano said that he owned a half million feet of land on the proposed line, and thought that the proposed system would be a good thing. One wire was very little obstruction. He had no objection to a conduit, of course, but did not want to hinder the construction of the line in any way. Mr. Horace W. Jordan, an owner of property in Brighton, urged that the rights asked for be granted in the interests of outlying property.

Mr. Hyde, in answer to Mr. Morison, said that the conduit took longer to build than the overhead system. Rapid transit is what the people are asking for, and if the conduits were to be required to the forks of the roads the company would not undertake to put it in this fall.

Colonel Henry Lee said that the deprivation of rapid transit for one winter would be only a hardship, but the erection of wires would be an injustice that ought not to be allowed.

President Whitney, of the West End company, said that the greatest demand yet made upon the company has been that of rapid transit. It was with the view of meeting that demand that the company reluctantly turned toward the cable system, and were proceeding in good faith to construct such a system when attention was turned toward the electric system. It is not alone the people of Brighton and Brookline that are interested in this question, but every passenger on the road, for it is proposed to try the electric system on a scale that will admit of no question as to its feasibility. The company hopes by the experiments of the coming winter to demonstrate the working of its system, so that in the spring it can be extended all over the city. He thought the gentlemen who now oppose the road will, when once it is in operation, deem it an advantage to property instead of a drawback.

Alderman Wilson asked as to the danger to life from the wire, and in reply Mr. F. J. Sprague, vice-president of the Sprague company, explained that experience in Richmond has shown that no harm is to be feared from accidental contact, many of his men and even he himself having received the full strength of the current without injury. He would be willing to guarantee no breakage from storms. There will be no danger to passengers from the wires in the car, the protection being perfect; nor would there be danger in an electric storm, the car being protected by "lightning arresters" of tried worth.

The hearing was then closed, and on motion of alderman C. W. Smith, the matter was referred to the board as a committee of the whole, with instructions to give a public hearing.

Several gentlemen who believe that the overhead wires which the West End Street Railway Co. desires to erect in connection with its proposed electric motor system will disfigure certain beautiful sections of this city, have placed a remonstrance in the several club houses of the city, and at the offices of Jackson & Curtis, No. 24 Congress street; Lee, Higginson & Co., No. 50 State street; Kidder, Peabody & Co., No. 113 Devonshire street, and other places, for signatures; over 100 signatures have already been secured.

The aldermen, as a committee of the whole, gave a hearing on the 17th inst. on the petition of the West End Street Railway Co.

Mr. Frank Morison, the first remonstrant, read the remonstrance signed by himself and two hundred others, against the granting of the rights asked for, upon the ground that the overhead system would disfigure the avenue and endanger the public safety. Mr. L. S. Dabney owned a house on Beacon street, near Fairfield, not on the line of the road. He frequently had gone over the route proposed and was familiar with it. The avenue, which had been improved at great expense for pleasure driving, it was now proposed to encumber with wires, and cars moving without visible means of locomotion, to the detriment of the safety of those who drove horses.

Two other remonstrants were heard, followed by Mr. H. D. Hyde, representing the petitioners. Mr. Hyde disclaimed any philanthropic intentions, as alleged by the remonstrants, but had no doubt that Mr. Whitney would be commemorated as a benefactor to Boston. He believed that the mass of people should not be deprived of better transportation facilities by the opposition of the few, whose sentiment led them to oppose the overhead system. The opposition was based entirely upon a lack of understanding of what they consider a mysterious, ungovernable power. The remonstrants were evidently not aware of the wonderful development made in the last few years in the application of electric motors, and of the many advantages that leave no question as to their superiority over all other kinds of power for nearly all purposes. He called attention to the fact that the motion of an electric car can be instantly reversed. On this understanding the contracts were made with the Bentley-Knight, Sprague, and Thomson-Houston companies.

The West End Street Railway Co. would agree to put in an underground conduit as far as the city built sewers, and would give bond so to do, to the city or to abutters.

He believed the electric system was necessary and practicable.

Cambridge is to have the first installment of the West End electric street lines on the overhead system, the contract having been signed by president Whitney with the Thomson-Houston company to equip the road between Harvard square and Arlington over North avenue, a distance of 3⅛ miles. It is expected that it will be in full operation in sixty days, and continued to Bowdoin square upon its completion. This company is now equipping electric roads in Washington, Ottawa, Syracuse, Des Moines, and other places, and has about thirty roads in successful operation in different parts of the country. The West End Railway Co. own more than eight thousand horses and many thousands of cars, and the slowness of proceeding to supplant horse power with electricity is partly due to the large investment which it involves. On September 25 the Board of Alderman, by a unanimous vote, granted the West End Street Railway Company the right to use electricity as a motive power in operating its cars.

Boston is very well supplied with police signal boxes, the Municipal Signal Co. is the successful competitor. Their boxes are placed against the walls of buildings, and do not in any way obstruct the streets or sidewalks, and are successful in working.

BOSTON, September 26, 1888.

CHICAGO.

A Novel Move to Reduce Telephone Rates; Killing Two Birds with One Stone.—The Telephone Company and the City Councils.—Rapid Transit before Council.—Professor Barrett on Electric Motors, and on Underground Wires.—Fire in an Electric Light Station.—A Long-Distance Telephone Company Incorporated in Illinois.—The Lowth-Stetho Telephone Co.—Dr. Cushman still Hopeful.—The Great Western Telegraph Co.'s Suits.—The Fire Underwriters' Association of the Northwest.—Mr. G. A. Mayo engaged as Electrician by the Van Depoele Company.—Electric Lighting in the Grand Opera House.—Other Electric Light Notes. New Companies.—A New Cable laid by the Telephone Company. Echoes of the Recent Electrical Convention.

A PETITION was circulated on South Water street, recently asking the city council to reduce the telephone rates to $75 per annum. The young man who presented the paper claimed to be a representative of a firm of lawyers. He asked each merchant who signed the petition to add his name to an agreement to pay $5 or $10 should the object of the petition be obtained. Signers to both papers were said to have been numerous. It has been asserted that some of the aldermen are behind the scheme, and that they hope to share in the profits of the firm whose agent was circulating the petition. Alderman McGregor, who is chairman of the council committe on gas and electrical lights, said: "There will be action on this subject without this petition. Before we adjourned for the vacation it was intimated to me by a member of our committee that the telephone company was willing to make a reduction in rates if we would give it permission to string wires and put in new instruments. The rents are now too high. There is nothing to be hoped for from competition. I think $75 would be a good rental."

This prophecy was fulfilled. At the meeting of the city council September 10th, alderman Landon introduced an ordinance granting to the Chicago Telephone Co. the right to extend its system, the wires to be laid underground except in the outlying districts. It was referred to the committee on licenses. The company is now operating without a license owing to the disagreements which have arisen between the council and the company. The proposed ordinance contained no limitation of rentals to be charged. In

presenting it alderman Landon said he introduced it because he thought the company should have legal authority in operating in the city. No consideration, he said, was offered the city for the privilege beyond an agreement to furnish city officers with telephones without charge. He said he favored amendments limiting rentals and providing for license fees. This is the attitude of one of the more moderate aldermen. One of the more sensible councilmen, aldermen Ernst, introduced an order directing the law department to take immediate action to secure the vacating of the injunction which prevented interference with the telephone company's wires. He also introduced an ordinance limiting charges to $75 per year for telephone rental. Both measures were referred.

An ordinance granting a franchise to the West Chicago Rapid Transit Co., which proposes to employ "steam power, electricity, or other species of power," was referred.

The license committee next took hold of the telephone question. The corporation counsel was directed to prepare such an ordinance for the regulation of the telephone service as would fix the annual rental at $75 and would protect the city's interests. The corporation council declined to express an opinion as to the right of the council to adjust the rates.

The committee on streets and alleys took up the question of rapid transit at the meeting of September 17. J. M. Hannahs represented the system which bears his name. He said the company had obtained the right of way on West Lake street and Milwaukee avenue. The ordinance asked for provided for a system sufficient for an electric or steam system. The right of way had not been verified, and no action was taken.

Professor J. P. Barrett, city electrician, is a thorough believer in the future of the electric motor in Chicago. He said recently :— "It is taking a firm hold in the city, and when electrical privileges are granted it will be generally adopted." The professor believes in the underground system as constructed in Chicago. When he was in Minneapolis, recently, he gave this advice in an interview with a reporter of a daily paper :—

"Take away all those unsightly poles along which your wires are now stretched and it will improve your streets to an extent that you can hardly realize before the thing is done. And then there is the great danger of the electric light wires and the serious inconvenience to the firemen when called to take care of great fires. The cost of putting wires underground is no greater than stringing them on poles ; it only costs more at the start in putting in the underground system. There is no inconvenience from induction in the underground system. There is really better insulation. From the fact that the different classes of wires run through ducts and chambers the separation is practically greater. When the wires are once put through they are there for a long time. They are easier taken care of. Electrical or any other storms do not affect them, and that is the great gain. I have wires in Chicago that have not been seen in seven years and they give as good service as ever. There is no liability of getting wires crossed and the distribution is made much easier. And even counting the first cost of the underground system as greater than the other, I really believe that in five years the underground would be the more economical. In short, the advantages of the system are too numerous to mention. But, of course, it is to be expected that the capital invested in other systems will fight this one at first, though it will be to the advantage of all in the end. In Chicago, we have 5,000 miles of wire underground. We burn 1,100 arc lights there, but have not an inch of electric wire above ground. We have 13 miles of the Dorsett system, and it does good service. We have electric light and telegraph wires in the same conduits, and the reports are that the service is exactly as good as if they were farther separated. We are making the change to the new system gradually. In two years we have taken out 1,300 poles. In the suburban districts there is not so much need of immediate action. The underground system will surely come in use all over the country. In New York, I see the electric light people are making a fight, but they cannot hold out long. Public protection, public convenience and public policy demand the change."

Fire was discovered in the north side station of the Chicago Arc Light and Power Co., about 1 A. M., September 10th. Four dynamos and three Ball engines were badly damaged. The loss is estimated at $6,000. The cause of the fire is unknown. The engineer and firemen left the station about 15 minutes before the discovery of the fire and locked the doors. About 155 lights were run from the station. Two of the circuits carrying 92 of the lights were cut into the main station, and there was no interruption of the service. The balance of the lights were out for three or four days.

The American Telephone and Telegraph Co. was recently incorporated in Illinois for the purpose of constructing long-distance telephone lines. The following gentlemen are interested in the company : Norman Williams, George L. Phillips, and R. C. Whitmore. Work has been commenced on the line to Milwaukee. The greatest care will be taken in the construction. Forty foot poles will be employed. The line is to be operated in connection with the Chicago exchange of the Chicago Telephone Co. and the Milwaukee exchange of the Wisconsin Telephone Co. The charge for communication has not yet been decided upon. Long-distance telephone service has not been successful heretofore from Chicago. The reason given for the failure is that the wires which connected the city with Kenosha, Racine, Milwaukee, and other places, were strung on poles which contained a large number of telegraph wires. The latter interfered seriously with verbal communication.

The Lowth-Stetho Telephone Co., with a capital of $5,000,000, has been incorporated by James Lowth, Edwin S. Brown, Jr., and Allen C. Knapp. The instrument which the company proposes to introduce is the invention of James Lowth, of Chicago. Its action depends on muscular action or vibration, and makes no use of the air waves. For this reason it is alleged it does not infringe on the Bell instrument. The diaphragm is dispensed with and in its use the instrument is held to the ear with the transmitting part resting upon the muscles of the neck. The company is not ready at present to give any further explanation of the operation of the instrument. The object of the company is to engage in a general telephone business. It is claimed that with the Lowth instrument conversation can be carried on over a distance equal to any over which communication is practicable with the Bell instrument.

Dr. Cushman, who claims to be the original inventor of the telephone, says he is not at all discouraged by the recent decision against his company and in favor of the Bell company. He is confident that Judge Blodgett's decision can be reversed on appeal as he asserts it contains many errors. His confidence and optimism never desert him.

Mention has been made heretofore of suits instituted by Elias R. Bowen, receiver of the defunct Great Western Telegraph Co., against stockholders to compel them to pay up their stock in order that claims of creditors may be settled. In one instance the receiver was successful. Recently 33 persons who are the unfortunate owners of this unpaid stock commenced a suit in which they ask that a decree of the court which compels them to pay on their stock be set aside. About 2,800 stockholders are interested in the outcome of this action.

The nineteenth annual meeting of the Fire Underwriters' Association of the northwest, was held in Chicago, September 12 and 13. The only mention of electric lighting was in a paper on "Rates and Rating," by Charles E. Bliven, of Philadelphia. He referred to the phenomenal growth of this mode of illumination, and said it formed a new risk which the members would do well to investigate.

The Van Depoele Electric Manufacturing Co. has secured the services of George A. Mayo formerly of Elmira, N. Y., as electrician. He has been engaged on the new incandescent system which the company will soon put on the market. Mr. Van Depoele continues with the company as consulting electrician.

Electric lighting has been introduced in the Grand Opera House. There are 850 incandescent lamps employed. Current is furnished from the Edison central station. There are 90 lamps for foot lights, 30 each of red, white and blue globes. The arrangement is such that either set can be used according to the requirements of the scene.

The Jackson and Wells street bridges have been completed, and electric lights illuminate them.

The new reading room of the Chicago public library has been opened. It is lighted by 120 incandescent lights.

Electric light wires caused a blaze in the lathwork in the ceiling of the Union depot in Chicago, August 29. The fire was extinguished apparently but broke out again after the departure of the firemen. The loss was about $350.

The Clinton Electric Light, Heat and Power Co., of Clinton, Ill., has been formed with a capital stock of $25,000, by Vespasian Warner, Clifton H. Moore, John Warner, Abner R. Phares, and Richard Buller.

Adolph Graeff, Alfred Graeff and E. Graeff, have organized the Chicago Electric Light Enlarging Co., with $5,000 capital stock.

The Royal Electric Co., of Peoria, Ill., has been incorporated, with $10,000 capital stock. The incorporators are Charles W. Robinson, James W. Smith and Gustav A. Shaefer.

Articles of incorporation have been issued to the People's Light & Power Co., of Chicago. The capital stock is $100,000 and the incorporators are Charles P. Dose, John F. Buhmann and Charles C. Fricke.

The Electric Machinery Co , of Chicago, has been incorporated. The capital is $100,000, and the incorporators are E. H. Haynes, Charles Steinbreiss and H. B. Cody.

The Merchants' Arc Light & Power Co., of Chicago, has been incorporated. The capital stock is $200,000, and the incorporators are, Martin Kingman, E. C. Heidrich, Charles A. Jamison and G. H. Schimpff.

The Nutting Electric Manufacturing Co., of Chicago, has been organized by Samuel E. Nutting, W. H. Foulke and J. W. Hefenburg.

The Chicago Telephone Co. has been laying a cable across the Calumet river to provide East South Chicago with telephone service.

The western members of the Electric Light and Telephone Associations report that they had a royal time in New York city while attending the conventions. Of the warm hearted hospitality of the New Yorkers they cannot say enough in praise. The western members of the Electric Light Association are particu-

larly well satisfied with the selection of Chicago as the place of meeting for the annual session. Chicago is a city peculiarly adapted for conventions, so at least the residents assert. Its citizens are hospitable, they know how to entertain, and they can always furnish accommodations for all who come. Of these characteristics the city is proud to a marked degree, and doubtless its reputation will be sustained when the convention meets.

CHICAGO, September 18, 1888.

LITERATURE.

REVIEWS.

Introduction a la Physique Expérimentale: Par MM. A. TERQUEM et B. C. DAMIEN. Unités, calcul des erreurs, mesure des quantités primitives, longueurs, masse, temps. Paris: A. Hermann, librairie scientifique, 1888.

THIS treatise contains 284 pages, besides a preface and an obituary notice of Alfred Terquem by Mascart. The preface states that material was largely drawn from foreign sources, preparing the reader for numerous references to familiar English and German authorities, and briefly illustrates the scope of experimental physics by the case of falling bodies and that of the changes of volume and pressure exhibited by gases.

The object of the treatise is instruction in fundamental operations, not to lay out a series of laboratory exercises. The introduction treats, in two chapters, of units and of errors. The chapter on units is in effect an abridgement of "Everett's Units and Physical Constants." Nearly half of it is devoted to electricity and magnetism, which subjects are introduced by a very neat statement of the reason for beginning with magnetic, and passing thence through electro-magnetic, to electrostatic measurements. The chapter on errors is mostly an application of the method of least squares. A simpler method, credited to Mascart, is given for determining the co-efficients of linear equations. In all the equations of a set, one of the unknown quantities, as x, has its co-efficient reduced to unity by division, the sum is then made, and from it each of the reduced equations is subtracted, thus eliminating x. The same process is applied to the remaining equations until y is eliminated. After the introduction comes the first part in three chapters, devoted respectively to lengths, masses, time. Ordinary instruments, such as verniers, the dividing engine, and apparatus depending on reflected light are detailed fully and satisfactorily; suggestions being made here and there. For instance, the decimal vernier for circles is advocated as a step toward adoption of a decimal graduation of the circle, and a table for converting decimal readings to usual measures is promised as an appendix. Instructions for mechanical processes are limited to adjustments of apparatus.

The only recipes are one for Elliott Brothers' gum-lac cement, and one for silvering glass. The cement is made by dissolving 40 to 60 grains of gum-lac in 100 c. c. alcohol. The materials are put into a flask, a cork inserted and tied fast, and then all is subjected to treatment in a water bath until solution is secured. The cement is solid when cold, but softens when heated. The process for silvering, which is given in minute detail, is credited to Dr. Martin, of Foucault's laboratory, but is quite unlike the Foucault process given by Witz in his "Cours de Manipulations." The book is well adapted for use in conjunction with manuals like Stewart and Gee's Practical Physics, for example.

CATALOGUES AND PAMPHLETS RECEIVED.

Mr. R. Eickemeyer's remarkable dynamo (an illustrated description of which appeared in the ELECTRICAL ENGINEER for March last) is the subject of a pamphlet issued by J. H. Bunnell & Co., of New York—selling agents for the machine. In addition to a list of the sizes offered and their capacity, with a price list, the pamphlet gives a detailed and well illustrated description of the dynamo, and concludes with a reprint of Mr. Eickemeyer's paper read before the Electric Club, New York, March 3, 1887, entitled "Some Remarks on the Magnetic Circuit in its Relation to a New Type of Dynamo-Electric Machine."

The O'Keenan Electric Manufacturing Co., 45 Broadway, New York, issues an eight page circular setting forth its primary battery for electric lighting. This company, to its great credit, is more modest in its claims than the swarm of primary battery men that has infested electrical circles recently. It offers no new and startling battery, with unheard of E. M. F. at little or no cost, but simply a new form of sulphate of copper battery, in combination with accumulators and regulating devices, for use in isolated plants of small size, where motive power cannot be obtained conveniently. The plan seems to be of sufficient interest to invite the attention of people concerned with small isolated lighting plants.

The "Pocket Handbook of Copper and Iron Wire in Electric Transmission," issued by the Washburn & Moen Manufacturing Co., Worcester, Mass., in convenient vest-pocket form, is a very interesting and useful little compilation of electrical information. The Washburn & Moen company have taken the trouble to get together in small compass a considerable mass of electrical notes and memoranda from widely scattered sources, arranging and classifying them very conveniently for reference. An "Index of Current Electrical Literature" is included, consisting of a list of many electrical and engineering publications in the English language.

POINTERS.

.... IT'S better not to know so many things than to know so many things that are not so.—*Josh Billings.*

.... IN America there are 6,000 electro-motors working machinery; in Great Britain hardly 100.—*Professor Ayrton.*

.... WE seem now to be rapidly approaching the time when optics will be recognized as a mere branch of electro-magnetism. —*Electrician* (London).

.... IF we read the history of the past, I think we can scarcely fail to observe that Nature has revealed herself in a greater degree to those who have worshipped her in her simplicity.—*S. Alfred Varley.*

.... As a matter of fact, in 99 cases out of 100, the telegraphist delivers to the editor of a newspaper "copy" far more accurate than the first proof of his own leader submitted by the printer.—*W. H. Preece.*

.... IT has been found from actual practice in electric light work in identical central stations, that 20 per cent. more work is required in the case where countershafting is introduced.—*Professor George Forbes.*

.... AN incredible amount of power is daily running to waste in this and other countries because many of the rapid streams of water are too far away from towns for their power to have been hitherto utilized.—*Professor Ayrton.*

.... IT has been proved, from the experience of numerous central stations, that during a considerable number of hours in the night the load on the engines and dynamos is only one-eighth part of the maximum load.—*Professor George Forbes.*

.... THE work of the engineer is not of the earth earthy, is not mechanical to the exclusion of science, is not unintellectual; but it is of a most beneficent nature, is consistent with true poetical feeling, and is worthy of the highest order of intellect.—*Sir Frederick Bramwell.*

.... LOOK at the furnaces and boilers of a great steam engine driving a group of dynamos, and estimate the energy expended; and then look at the incandescent filaments of the lamps excited by them, and estimate how much of their radiated energy is of real service to the eye. It will be as the energy of a pitch pipe to an entire orchestra.—*Dr. Oliver Lodge.*

... I SAY that the introduction of prime-movers as a mere substitute for unintelligent manual labor is in itself a great aid to civilization and to the raising of humanity, by rendering it very difficult, if not impossible, for a human being to obtain a livelihood by unintelligent work,—the work of the horse in the mill, or of the turnspit.—*Sir Frederick Bramwell.*

.... HENCEFORTH I hope no learner will fail to be impressed with the theory-hypothesis—no longer—that electro-magnetic actions are due to a medium pervading all-known space, and that it is the same medium as the one by which light is propagated and that non-conductors can, and probably always do, as Professor Poynting has taught us, transmit electro-magnetic energy.—*G. F. Fitzgerald.*

.... THE American plan of basing a conclusion on experience rather than on anticipations, is not a bad one, and if we follow that plan, then taking into account that there are 75,000 arc lights alight every night on the Thomson-Houston high potential circuits throughout the world, and the comparatively small number of people that have suffered in consequence, we are compelled to conclude that high potential now is what 30 miles an hour was half a century ago—uncanny rather than dangerous.—*Professor Ayrton.*

.... THE agitators who want legislative interference against the use of high tension dynamos, should be consistent, and if the protection of human life is their real motive, they should attempt also to obtain legislation against the manufacture and use of high tension dynamite, nitro-glycerine, and other similar explosives; also against the use of gasoline lamps, burners and stoves, all of which produce their quota of victims almost daily. Further, against horse and foot races, rowing and swimming matches, base and foot-ball games, athletic sports, etc.—*Dr. P. H. Van der Weyde.*

NEWS AND NOTES.

THE NATIONAL TELEPHONE EXCHANGE ASSOCIATION.

TENTH ANNUAL MEETING, HOTEL BRUNSWICK, NEW YORK, SEPT. 4 AND 5, 1888.

The association assembled at 11 A. M., on Sept. 4th, the President, Mr. Henry Metzger, of Pittsburgh, in the chair.

President Metzger introduced Mr. Henry C. Davis, president of the Electric Club, of New York, who extended on behalf of the Electric Club and of the citizens of New York a cordial welcome in the following words:—

Mr. Davis—*Mr. President and Gentlemen of the National Telephone Exchange Association:* On behalf of the Electric Club of New York I am here to confirm our invitation of a year ago and extend to you a cordial welcome to our club, and I trust that you will enjoy yourselves there to the extent that your predecessors of last week, I believe, have done. In extending our invitation to you, the intention was that you should hold your convention in our lecture room, but I am happy to congratulate you upon your number being too large to be comfortably accommodated in our limited quarters. I also want to congratulate you upon the fact that you have only one parent company to deal with instead of a conglomeration of parent companies, as the National Electric Light Association has, each believing that their own apparatus is the best and the one that you ought to adopt and use. You have to a certain extent a kindred interest with that association, and I trust that your struggle with the underground conduit system will be a success.

President Metzger, on behalf of the association, returned thanks to President Davis for the invitation.

The secretary, Mr. C. H. Barney, then read his report showing that there were upon the roll 86 active, 5 associate and 29 honorary members. The routine work of his office had been much the same as the previous year. The publication of the *News Letter* had been continued, and it had been his privilege not only to visit the more important exchanges in New York and vicinity, but many others at distant points including Boston, Providence, Philadelphia, Pittsburgh, Cincinnati, Chicago, Minneapolis and St. Paul. The receipts of the year were $1,937.69, and the expenses, $1,953.17, thus drawing slightly upon the surplus of the previous year. The report was accepted and filed.

The treasurer, Mr. H. L. Storke made the following financial statement:—

DEBITS FOR YEAR.

Amount collected for dues	$1,900.00
Initiation fee	10.00
Extra sales of proceedings	27.69
Total	$1,937.69
Balance in hand	37.33
Total	$1,975.02

CREDITS FOR YEAR.

Secretary's salary	$1,200.00
Rent for office	120.00
Printing Pittsburgh proceedings	221.25
Other printing	138.80
Office expenses, postage, etc	152.51
Stenographer—Pittsburgh	59.25
Other expenses	61.36
Total	$1,953.17
Balance on hand, Sept. 4th, 1888	$21.85

Mr. Henry Metzger was then unanimously re-elected president. In accepting the office Mr. Metzger said:—

ADDRESS BY THE PRESIDENT.

I can only thank you for this evidence of renewed confidence on your part in re-electing me to the office of president. It is usual on occasions of this kind for a retiring president—to offer remarks upon matters germane to the purpose for which we have assembled. Every city, town and village in our country, from the Atlantic to the Pacific, from the borders of Canada to the Gulf of Mexico, gives visible evidence of the work you have performed in developing the telephone business. But I do not intend to take you back and recall the history of the past. It is sufficient for me to ask you to go to that period of time, one year ago, when we were assembled in the city of Pittsburgh. It was a time pregnant with uncertainties and doubts as to what the status of the telephone companies would be for the coming year. It is true that every Circuit Court of the United States, wherever the American Bell Telephone Company had brought suit, had granted preliminary and final injunctions against infringers, whether defended by government aid or by private wealth and influence. Yet there still remained a doubt as to what the final outcome would be. The uncertainties of the law were too well known to all of us, and although our faith in the righteousness of our cause was firmly grounded, yet some unexpected resistance might develop that would weaken our faith in the wisdom, justice and honesty of men. After a long, bitter and expensive struggle the day of judgment came. It was delivered by that honest and eminent jurist, Morrison R. Waite, the late Chief-Justice of the Supreme Court, whose memory, I think, the telephonic fraternity should revere, and over whose grave we can all shed the tear of regret at his untimely death. But before yielding up his life he placed the seal of judicial authority on the scroll of fame that bore the name of Alexander Graham Bell as the inventor of the speaking telephone. (Applause.) And in this connection I cannot forbear saying to the association that we are much indebted to those two eminent attorneys, J. J. Storrow and E. N. Dickerson, for their masterly knowledge of the science of telephony, and their keen analysis of the evidence as produced in the various causes which they argued. Since that time we have had a period of repose; a feeling of security has prevaded the minds of our stockholders in regard to the safety and permanency of their investments. In many other cases the directors of companies have entered into a more liberal policy, one more in accord with the necessity and requirements of the business. In some cases, notably in New York, Chicago, Baltimore and Pittsburgh, new buildings have been erected suitable for carrying on the business in which we are engaged. In some other cases underground systems have been laid—either a new plant or extensions of existing ones. Multiple switch-boards have taken the place of old systems that were a constant source of discomfort to subscribers and telephone managers. In some other cases larger poles have been erected, copper wire has largely taken the place of iron and steel, and good insulation the place of poor or perhaps none at all. But while much has been done, much more remains to be done in the next three or four years, if the members of this association desire to retain control of the business. In the sphere in which we move and perform our work we may be kings, but there is a greater circle beyond that in which a constant power is being exerted that will in a very short and limited time compel you—compel us all—to give the best of service and at a cheaper cost; so cheap, in fact, that your competitor of the future may well hesitate at the threshold before entering the field with hopes of successful venture. But the day of the inevitable conflict is coming, and it is your bounden duty to your stockholders and in justice to yourselves to prepare for that day. The maxims, "In days of peace prepare for war," or "Make hay while the sun shines," are worthy of your serious consideration. It will not do for you to fold your hands and rest content with the fruits of the legal victories of the American Bell Telephone Company. The competitor of the future will be no less relentless than the infringer of the past; watching every movement that you make, noting every step of progress, he is but waiting for the day and the opportunity either to divide the business with you or perhaps to absorb it entirely. I now, gentlemen, desire to return again my thanks for your very kind treatment of the chairman—from the time I first entered your service at Niagara Falls to the present moment. (Applause.)

The following additional officers were then elected: vice-president, W. D. Sargent; treasurer, H. L. Storke (re-elected); to the advisory committee, M. F. Tyler (re-elected); to the executive committee, S. M. Bryan, W. J. Denver, G. M. Stone and C. F. Cutler.

Invitations were then read from the American Telephone and Telegraph Company, for a drive in Central Park; from the Western Electric Company, to a dinner after the drive, at the Mount St. Vincent Hotel; from the Metropolitan Telephone Company to an excursion up the Hudson and dinner, including the spectacle "Nero" at Staten Island. These, together with the invitation of the Electric Club, were accepted.

Mr. F. A. Pickernell then read a paper on "Notes on Telephone Batteries." (See page 482.)

Mr. Gifford—Mr. Pickernell mentioned the fact that he used three Leclanché cells usually with the long-distance transmitter. I started out, rather on my own hook, to see how many cells were wanted. I commenced with 1, 2 and 3, and carried it up to 4, and found that 4 gave the best result. While I do not wish to have the association espouse the interest of any particular battery, I would like to know what battery has been found to be the best for long-distance transmitters. As a matter of fact we want to get at the very best battery—what has been found to be the best.

Mr. Seely—The Metropolitan Telephone Company, of New York, are putting in a storage battery for their transmitters, especially for the exchange work. We are about to use a cell we call "Type D," giving 7 amperes of current, an internal resistance to about $\frac{5}{1000}$ ohm, and 2 volts. Those batteries are about 7 inches high by 12 inches square.

Mr. Lockwood—I notice one point in Mr. Pickernell's paper which, since it differs from my own experiments, I think it proper to refer to especially. If I recollect aright he stated that we were to be careful in the use of Leclanché batteries not to use too much sal-ammoniac. If by using too much he means that we are not to fill the jars full and then try to moisten it, I agree with him. If, on the other hand, he means that we must be very chary about putting sal-ammoniac in, I cannot agree with him. I have found in the course of some 13 or 14 years of experience

in telephony and otherwise, that the amount which the dealers (especially the Leclanché Battery Company, who are very careful to send out nothing but good material) send out is exactly the amount which it is proper to use, and that we can neither diminish that nor increase it with advantage. It is true that crystals will form upon the zincs and upon the lower part of the carbon, but as long as crystals of sal-ammoniac only fall on the zinc no great harm will come. It is also a fact that when there is little sal-ammoniac in the solution, oxychlorides of zinc and ammonium at once form on the zinc, and these salts, being insoluble, take away just so much of the conducting surface of the zinc, and thus increase the resistance of the battery, besides preventing the necessary consumption of the zinc, which is absolutely essential to the proper working of a battery. I dare say when Mr. Pickernell comes to restate his views they will be found to be not far from those which I have enunciated. I am also very glad to note from what Mr. Seely says that the Metropolitan company is making an experiment in the way of using secondary cells. I should like to request Mr. Seely to make a careful observation of the working of such batteries, so that at our next meeting we may be enabled to know something about it.

Mr. Pickernell—I would state that I quite agree with Mr. Lockwood in respect to his statement about the use of sal-ammoniac. I mention that fact because I found that it was not infrequent for telephone inspectors to put in two of those packages of sal-ammoniac instead of one, thinking that by so doing they might possibly save a trip there in a short time. It is only about two weeks ago that I found 3 cells of battery which we were using on a long-distance transmitter in which the zincs were entirely covered with crystals of sal-ammoniac. My attention was called to that state of things because the transmitter would not work at all.

In reply to the question about the number of cells to be used with long-distance transmitters, we find, if we use low resistance batteries, that 3 cells are as good as 4, there being practically no difference. But if you have batteries in which the resistance is increased from any cause whatever you will find that 4 batteries are better than 3.

Mr. Gifford—One word in regard to sal-ammoniac. A short, practical rule that I have adopted is to allow an inspector to put in no more sal-ammoniac than you can dissolve in water. I do not leave any at the bottom of the cell at all. I found as Mr. Lockwood says he found, that some will load up a cell with 2 or 3 charges, so that they will not have to go back. I only allow them now to put in as much as you can dissolve. That varies according to the kind of water in different towns. In a town where you use lime water it will not hold so much sal-ammoniac in suspension as pure river or rain water will.

Mr. Thornberry—In my experience I rather favor the disposition of the batteries described by the gentleman who last spoke, in placing just enough sal-ammoniac in the battery to keep it doing its work. I want to say, in reference to the long-distance telephone, that where hard work is being done the Leclanché battery will hardly answer the purpose, if it is in an exchange where it is used frequently; but a 4 or 6-cell gravity battery will serve the purpose. That is to be determined by the length of the line in which you wish to work it or the condition of the battery itself. The sulphate of copper battery, or gravity battery, has to be constantly at work or it will polarize itself. If it is constantly at work and cleaned once a week, the gravity battery will give splendid results and give you splendid transmission for your long-distance telephone.

Mr. Bailey—The point aimed at seems to be to get an effective working battery of low internal resistance. Has any one experimented with the Leclanché batteries on any kind of telephone in multiple? In using them in multiple you would get much lower internal resistance, I should say, and. of course, a greater quantity of current.

Mr. Lockwood—Some two or three years ago the chief clerk of our company, Mr. R. W. Devonshire, sent me two or three transmitters with the instruction—I don't know whether it was directed to me specially, or whether it was in the nature of a circular—which gave me the exact information how much battery I ought to use for the long-distance transmitter. I did not follow the instructions with great care, and I tried them with a number of cells of different kinds. I tried them with 1, 2, 3 and 4 cells of Fuller and different bichromate combinations. I tried them with 1, 2, 3, 4, 5 and 6 cells of Leclanché and other similar batteries, and I tried them, as Mr. Bailey has spoken of, 3 in tandem and 2 abreast, 3 in series and 2 in multiple arc, and I found that while that arrangement was new it worked beautifully. It furnished the proper amount of current, or at least it furnished a very good amount of current, and it worked very nicely. But when that battery grew a little older, I found that it did not work as well, because it was impossible to make the two sides work alike; one side got a little stronger and kept getting a little stronger than the other. Consequently, instead of both parts of the current going one way, the stronger battery took a notion to polarize or go against the current of the other side. A better way would be to do, what I am surprised battery manufacturing companies have not done before, *i. e.* to make a larger Leclanché cell. Possibly they have done it before, but it has not got into the market. A demand has come, however, for a Leclanché cell about twice the size of the present cell. I think that we shall have to put our trust still in the peroxide of manganese battery until we can find that peroxide of lead is as constant as peroxide of manganese, and it is a proper thing, I think, for manufacturers to consider whether they had not better increase the size of them.

Mr. Seely—The present plan of the Metropolitan company is to make an inspection once every month. The solution is thrown out and a new solution made up. Each inspector is provided with a measure holding four ounces of sal-ammoniac. We guard against overcharging the batteries in that manner. We find that the Gonda porous cup is about as good as the Leclanché battery. Taking the current at the electrodes of the battery we find that we get 1.7 volts with an internal resistance of 1.7 ohms. After using that battery through a resistance of 8 ohms for five minutes we find that the voltage falls to 1.3 volts, the current to .5 ampere and the internal resistance has increased to 2.6 ohms. Short circuiting of the battery for an hour and five minutes we get .3 volt and .3 ampere and 1 ohm internal resistance. That battery was far ahead of any we experimented with.

The convention then adjourned till 2:30 P. M., and remained in executive session until 5 P. M.

SECOND DAY, WEDNESDAY, SEPT. 5.

The meeting was called to order by President Metzger at 10 A. M., and Mr. C. L. McCluer read a paper on "Dynamo Current Interferences with Telephone Systems, and Means of Relief." (See page 483.)

Mr. Lockwood—I would like to ask Mr. McCluer whether he has made a point of having his return conductor parallel with his main lines.

Mr. McCluer—Of course, in every instance. I have only, so far, in the Richmond exchange provided one common return wire; that is, up Ninth and Broad streets, and up Broad street to the western extremity, with branches radiating along the lateral wires. Of course this wire is carried on the same pole and parallel to all the wires connected to it.

Mr. Lockwood—Mr. McCluer is quite right, I think, in attributing a certain amount, at least, of the disturbances, and perhaps, nearly all the disturbance, occurring from the electric railway to absolute leakage of the electricity from the rails to the telephone wires; but like nearly every person who has at one time adopted one theory for certain phenomena, and at another time another theory, I think he has become an extremist, and, as is usual, the mean is the correct view. A great deal of our disturbance on telephone lines is still due to the old enemy—induction, and although the telephone business is eleven years old now, induction is still just as strong as it ever was. The trouble that electric lighting, and especially arc lighting, has given to telephone men are of two-fold character; first, of the character which disturbs the conversation; and secondly, of the character which destroys the wires and apparatus. Within the last year or two we have become apprised of another enemy in the lighting camp, namely, the alternating current used for incandescent lighting, and these are used not only through converters, but also on direct circuits. The telephone line which runs from the Malden central office, in Boston, to my own house is a very much disturbed line indeed, and I allow it to remain there, so that I can study the phenomena. But we formerly had a Thomson-Houston direct arc lighting machine, with a three-plate commutator, and the noise was bad then; but lately they have taken to lighting Melrose, where I live, with incandescent lamps placed in a direct circuit and operated with an alternating machine, and the noise is now tremendous, because the alternations are almost as quick as the telephone alternations, namely about 200 per second.

A paper was then read by Mr. T. D. Lockwood on "The Electrical Relations of Telephone and Electric Light and Power Circuits and Railways." (See page 485.)

Mr. Lockwood (after reading his paper)—Now one word as to Mr. McCluer's device. It is true that the evil he has had to encounter is actual leakage from the rails, and that it has manifested itself both by affecting the apparatus and by affecting the conversation, and there was no reason even before he tried his device to doubt that it would do its work. I do not know whether it has totally eliminated the noise, but if it softened it down fifty per cent., as he says, if it has made it bearable so that people can talk, a great deal has been done. Since the beginning of the telephone business, I think some six hundred patents have been issued for different forms of telephone, and I think perhaps from three to four thousand patents for telephone appliances, out of which perhaps two hundred have directly or indirectly referred to apparatus for reducing, eliminating or neutralizing induction. A great many are not worth the paper they are written on. But this device of a return circuit I think probably was first indicated by the old way in which those of us who were telegraph men used to run what we called combination locals. We used to have a number or combination of local battery cells, one for each sounder, and we would bring them all

back over a common wire. A little later, when the telephone business began, quite a number of people, myself among others, patented a system in which a common return wire was provided for a group of circuits. That was in 1880. In the application for a patent that I put in, we had a narrow escape from an interference with some of Mr. Scribner's applications for patents on devices which afterwards went into use throughout Indiana, Ohio and Illinois as the Wiley-Scribner Telephone Exchange system. Since then, the very idea of using a common return as an induction neutralizer has been patented by a man named Bentley, and within the last six months the American Bell Telephone Company bought that patent with a lot of others (the American Bell Telephone Company buys patents so that its licensees can use them). I have not made these observations with the idea of belittling Mr. McCluer's invention, because there is not the slightest doubt that he invented it independently and for his own work, but simply to say that none of the rest of you, if you wish to use it, need hesitate for fear of trenching on his prerogatives, because it is open to every one of you who are licensees of the Bell telephone company.

Mr. Durant—We have for three years used that device and have it in use now. I think it is applied on twenty-four wires. It came into use from the interference of the Heisler incandescent system, which uses an alternating current. Presuming, of course, that the Heisler circuits were constructed in conformity with the rules of the Board of Public Improvements, namely, in close parallel lines, we did not examine them, and we put this common return wire in use, and we found it very effective. In the meantime we found that Mr. Heisler had one side of his circuit on the side of this street where our wires were, and the other on the other side. We made him correct that.

Mr. Bailey—There is another point I want to call your attention to—that matter of danger of dead wires in relation to lightning trouble. We have had a little of it out in our country. Of course, we have a system that covers a good deal of country, and is made up largely of country lines, and in the changes in telephone business dead wires occur with us, as they do with every one else, and dead wires are sometimes a good deal more costly than living ones. The usual course of proceeding when a telephone is discontinued is to take the telephone out without making any provision for the wires which are left standing. The question is, - During a thunderstorm, what will become of a current that may gather on that wire without any connection to the earth? It certainly has to discharge somewhere, and in discharging, it is likely to do a good deal of damage. It strikes me that it is similar to the case of a defective lightning rod—a lightning rod which has no earth connection. We have a case of that kind where a loop was taken out on one of our lines. The line got charged from a thunderstorm, and the lightning followed in on those open wires and struck a child and knocked it insensible. It recovered without any apparent damage, but it was a thing that, it strikes me, should be guarded against. Wires of that kind should be removed from the premises.

Mr. Farnham—Mr. McCluer suggested an idea, which I think, may be misunderstood and might be misleading. He said that in a large place where there were several electric light wires running one might offset, in a certain sense, the induction from another wire, and so the difficulty need not be as serious as it would be where there was only one circuit. I have found in several cases, in looking up these same troubles, that the electric light people have taken that ground and have said that their system was all right, because, notwithstanding the fact that each circuit was a belt circuit, yet the several belt circuits were on the same pole with what they call the positive pole of the machine, and that consequently the interference of one line would be neutralized by the interference of an entirely separate circuit. Of course, we will find, if we try it, that this is altogether false, because we cannot have two machines running at precisely the same speed and the changes of current coming together at precisely the same moment of time, and while there may be, in listening at a telephone, a moment when the noise is less, the next moment it will be very severe. One of the noisiest exchanges that we have is where the circuits run in belts on the same poles, and yet there is no balance whatever. I speak of that because unless we understand it thoroughly and are ready to answer the electric light people's question in that matter, we may get ourselves into trouble. The only way to remedy that is to take two of those circuits and make a metallic circuit, if there happen to be four or six circuits, taking the same general route, of course, that can be arranged so that there will be a metallic circuit of each individual circuit on the same poles without materially increasing the obstruction. In speaking of the electric railways, nothing was said, I think, in the paper or in the remarks about the feed wire. Sprague's system uses a feed wire. I do not know about the Richmond system, but I do know one system in New England where this feed wire is also a bare wire. It certainly is bad enough to use a bare trolley wire with a grounded circuit, but where the excuse is for using a bare wire in places where our wires are liable to touch them at any time I cannot conceive.

Dr. P. H. Van der Weyde—I am in a position to mention certain results in regard to a general return wire which I obtained in a series of experiments that I made some years ago, with the purpose of economizing the wires with a double metallic circuit, and having one general return wire. I found that if a general return wire, substituted for a ground wire, is not close to the direct wire, it is of no use. I found that it is only reliable when the wires are all near together as in a cable. Therefore, I adopted the system of making as far as possible a well insulated return wire of low resistance in the centre.

Mr. Seely—I would like to state our experience with a common return wire for subscribers. In New York city, in 1885, we put up a Patterson cable. In those days they made a cable with a large centre core. I think it was a No. 6 wire. We connected to that cable some five hundred subscribers. We grounded that central core in the central office. While that cable worked fairly well and cut down the induction and cross-talk and leakage, we discovered by ringing up a subscriber on a long wire, that we would also ring up a subscriber on a short wire, and that with two wires of the same comparative resistance, if two subscribers would attempt to talk at the same time, the cross-talk between those two relative wires would be very severe. We immediately abandoned the scheme and considered it useless. I would also like to state, while I am here before the convention, that I presume in New York city we have a larger number of electric light wires in the air than are in any other city in the world. All systems are represented here. It is the policy of the Metropolitan company to grant pole privileges to those companies. We have a blank form on which they make application to the company, and by so granting them permission to erect their wires on the property of the Metropolitan company we are in a position to dictate to them; we tell them exactly how we desire their wires to be constructed; how many lamps on each circuit, whether we should divide the lamps in positive and negative sets. The East River Electric Light Company have about 2,200 or 2,500 attachments on our poles, and their wires are built in the most excellent manner. We are suffering very little from the leakage from their currents. They use the Thomson-Houston system, and are giving us no trouble whatever.

Mr. Thornberry—Providing this return wire is almost as expensive as it would be to the electric light company if they returned their wire, which in equity and justice they should do, it seems to me that the telephone companies should not establish a precedent which the electric light companies may force them to follow afterward. It is only right that they should put their systems in such a condition as not to interfere with your service. If you are on the ground first you have vested rights. I think the convention ought to take some action in coöperation with the National Electric Light Association. I was almost ready to make a proposal that this association appoint a committee who might meet a committee from the National Electric Light Association to discuss the matter of providing methods and means whereby we might harmonize the interests of the two associations.

Mr. Lockwood—We cannot deal with an association in these matters. We have got to deal with separate companies and individuals. An association—even this association—has no authority from any one of its members, though we are bound together by common interests and common ties, much less can another one with several major conflicting interests, and several hundred minor conflicting interests, behind its members. It would be at this time a thoroughly useless and futile thing to do.

Mr. McCluer—If the members of the association will allow me, I would like to occupy a few moments of their time in making a little plainer one or two points that have been brought up since the discussion began. In the first place, with reference to the metallic circuit and the common return wire; as a matter of course, I have known for years that the metallic circuits and common return wires have been in use. I did not suppose that I was originating anything new in devising a simple metallic circuit or a simple return wire. But I do believe that I did devise something new when I devised what I call a compound metallic circuit—a metallic circuit with one wire only to serve the purpose of a return wire with an unlimited number of wires attached to it. I also believe that I have devised a new idea in substituting a metallic conductor in place of the earth without any earth conduction at all. I am perfectly familiar with Mr. Bentley's and Mr. Marbury's patents. They are both for anti-induction cables, and to apply these systems to telephone exchange plants would necessitate the entire reconstruction of the plants. The system that I propose to use does not require anything of the kind—not a solitary wire on poles or house-top fixtures has to be changed or altered in any way; all that has to be done is to put up one additional wire for every wire—I do not care what the number is, one or two, or a dozen, or hundreds of wires on the same route, and the only change that has to be made in the system is the simple substitution of this common return wire for the ground. To prove that, I will state that I have in the Richmond telephone exchange to-day eighty-seven stations connected on to a single return conductor. That conductor starts from the central office with a number 4 covered copper wire extended to a distance of half a mile from the central office. Connected to that is half

a mile of No. 6 covered copper wire, and continuing the wire runs a mile from the office; beyond that it is my intention to use a No. 8 copper wire to reach the various stations of the subscribers. I have now one such wire only in use in Richmond, extending from my central office up Ninth street to Broad, and thence out from Broad to the terminus. On that wire I have eighty-seven stations connected just exactly as they were before, to the earth, and by means of a plug switch which I have in the central office I can use that common return wire either as a general ground wire, making all these subscribers' wires take earth at the central office, or, by removing this plug, I can disconnect them entirely from earth and use them as metallic circuits. Of course I could not conceive it possible that no one had tried this arrangement before; it was so simple in itself. It was only after making the experiment I did, that I induced our officers to allow me to make this practical test. When I made my first practical test and connected my first ten or twenty stations on the first half mile of copper wire, I was exceedingly interested in how the result would be. The very next night after it was done, I went to the central office. I spent nearly two hours, from ten to twelve o'clock, with four or five of my inspectors, going to different stations that we could get into on this line, and all of them talking over the different circuits at the same time, all of them ringing over different circuits, and doing it all simultaneously; there was no interference. I have repeatedly gone to my office at night, taken this plug out of the switch and disconnected the systems from the ground entirely, got two, three, four and six people to talk at the same time on different wires on that circuit, and not one could hear a word that the other said—not as much cross-talk on that as on wires I have running down Carey street on the same pole. Now that is a fact. Of course, as I stated, I made inquiries from some of my electrical friends that I thought might possibly have heard of the adoption of this principle before I did, but it was new to them, as it was to me, and I never had seen any intimation of anything of the kind being done, in any of the public prints, although I am a subscriber to two or three technical journals. I then disclosed the plan to our executive officers, and had a good deal of correspondence with them with reference to the matter before any decision was arrived at. During the progress of our correspondence I heard that Mr. Durant, of St. Louis, had tried the return ground system, and as it was told me, without any result. I was also told that an English electrician, a telephone man, had reported that in England they had tried the same thing and had found they obtained a better result by connecting the two ends of this common return wire to the ground also, using the earth and the wire together. Well, that was a revelation to me. I thought possibly there might be something in it. I had not thought of trying it before, but I did try it, and just the very moment that the earth was connected on the wire again, the same interference that we had before showed itself, but the very moment the earth was disconnected from the common return wire, all this interference disappeared. I am only giving you facts, and facts that I have verified in every way that I can. Mr. Lockwood says he did not understand me to say that it was my intention or expectation to connect any considerable number of wires to the same line. I do propose to do that. I propose to have only one wire of large conductivity on every line of poles. It does not matter whether the pole carries twenty-five wires or two hundred and fifty wires.

Dr. Van der Weyde—I wish only to state that according to my experiments it is possible for twenty or thirty operators on a telephone line to communicate with one single return wire. My experiments were made five years ago in anticipation of the necessity of putting the wires underground. Then I got, by the kindness of the telephone company, the use of a number of cables containing some hundred wires and a central wire. They call it the Patterson cable. But the results were unfavorable, for the reason that this cable was connected at both ends with the ground.

Mr. Reilly—I would like to say that something over three years ago we had occasion to run a common return ground, such as Mr. McCluer described, to overcome the induction from the Delany synchronous multiplex telegraph on a line parallel with ours for about five miles. We ran a No. 12 copper wire for about four miles, and connected it to six stations, and almost entirely overcame the noises from the telegraph wire, and suffered no interference whatever from ringing from one station to another, and had no interference from cross-talk. That line is still in use and giving satisfaction.

Mr. Seely—Mr. Lockwood referred in his paper to the great disadvantage and the great amount of trouble caused by dead wires hanging in the way. I would like to say that I think every city should have a subway commission. Of course we have one, though it is very much abused. But they are removing the dead wires fast in New York city; they take down the poles and wires, and the companies have no trouble whatever in removing the dead wire. They do it for them.

The secretary then read a paper by Mr. W. D. Sargent, on "Underground Work in Brooklyn, N. Y." (See page 488.)

Mr. L. F. Beckwith followed with his paper on "The New York Subways." (See page 487.)

Mr. E. F. Sherwood then read a paper on "The Telephone Exchanges for the City of New York." (See page 489.)

Mr. Durant—I want to speak of the system we have in use between St. Louis and East St. Louis. The exchange at East St. Louis consists of only 50 subscribers, and about 90 per cent. of the traffic of that exchange is with St. Louis. Ordinarily in the Law system the trunk line business is done over two receiving wires, one from exchange A and exchange B, and the other from exchange B and exchange A, and we have that same arrangement between St. Louis and East St. Louis. However, the ordinary method is for the receiving operator to throw a telephone and transmitter into the sending call wire and give an order, expressed by numbers to the receiving operator. In the case of East St. Louis, which is occupied by an open circuit call wire which runs to the operator at the central office at East St. Louis, that line is extended—it is not grounded at East St. Louis—but it is extended to the receiving operator at East St. Louis. Consequently the order for office at East St. Louis is heard by both operators—by the one at East St. Louis and also by the one at St. Louis. The direction of the traffic is indicated by numbers. The numbering series at St. Louis commences at 100 and runs up to 5,000, while the numbering at East St. Louis is confined to the 5,000 series. When the subscriber at East St. Louis gives his order, of course the direction of the connection is expressed in the way given. That order is overheard by the operator at St. Louis and without any word between them they select the lowest number idle trunk line, and the connection is made without any word passing between them. If any of you can beat that on the trunk line service we would like to know it.

Mr. Seely—I would like to state, Mr. Chairman, that we are using a call wire precisely as Mr. Durant describes, with the exception of the St. Louis circuit. The operator, who could formerly handle only 7 trunk wires, is at the present time handling 50 trunk wires. Instead of sending and receiving trunk wires she virtually becomes a switchman at No. 1 exchange, while the operators at No. 2 exchange are simply calling into her from the call wire. I presume the company is saving $10,000 or $12,000 a year in salaries on the trunk line system alone.

The secretary then read a paper by Dr. S. M. Plush on "The Telephone." (See page 490.)

Mr. Durant—I do not believe there is a class of men in the world who appreciate the telephone less than the men engaged in the business. The reading of Dr. Plush's paper called to mind a statement made to me by the manager of one of the largest and best papers in the country, published at St. Louis. He told me that on the night of the earthquake—it occurred about 12 or 1 o'clock at night—that inside of two hours he called up 103 stations in various parts of the city, and got two columns of very interesting matter showing the effect of the shock in various parts of the city. That will perhaps show its value in one direction. The capacity of an operator under great stress was decided in our exchange, I think, last January, under the direction of Mr. Doolittle, and if any of you have not made that test I would suggest to you to make it, to show the number of connections that can be made in a given time by a single operator. On this test 53 were made in five minutes.

By a vote of the association, Minneapolis was selected as the place of meeting next year

A paper was then taken as read by Mr. McCully on "An Interesting Judicial Opinion as to the Rights of a Telephone Company against House Movers."

Mr. Kerr—The question of taxation by the boroughs, by the cities, by the townships and by the state, has caused the Pennsylvania Telephone Company a good deal of trouble. I believe the law in Pennsylvania is in a mixed up condition, and it is probable that members of the convention here could throw some light upon the subject which would assist us in determining what course we ought to pursue. The Pennsylvania law, I believe, as to the taxation authorized by boroughs is that boroughs can only tax after the analogy of the taxation by the county commissioners. The act signed by the governor of Pennsylvania on the 24th or the 25th of May, 1887, gave the cities of seven classes the right to tax telegraph, telephone, electric light and power companies; that is to charge a license tax. There are, however, decisions by the Pennsylvania courts which show perfectly distinctly that the plant of a corporation cannot be taxed. Notable among these is the Coatesville company's decision which is constantly cited by the Western Union and by other companies interested in the matter. It was there decided that plant was capital and could not be taxed. Now, almost every city and borough in which our company is interested is trained to tax and is trained to institute a pole tax. The Western Union Telegraph Company has recently secured a decision of the Supreme Court of the United States that a pole tax is illegal. I believe that is on the principle that the line is an interstate line and the business an inter-state business. However, there is another principle on which the Western Union Telegraph Company is now standing, that the boroughs and cities have a right to tax and to charge this license tax only on a police principle, and this license tax cannot be a tax per pole but must be a tax on the telegraph property in proportion to the value which the telegraph property bears to the other property taxed on the

police principle in the city. This has reduced the Baltimore & Ohio Telegraph Company's tax in one city, I am told by J. B. Stewart, superintendent of that company in Baltimore, to the sum of 39 cents, whereas the effort to tax was something like a $1 a pole. If any company represented in the convention can name any principle which governs other states or which is established by the law of other states, which would form a precedent, as Pennsylvania law is undecided, it would be very useful. If any person, also, has seen a decision of the Supreme Court of the United States which is to the effect that the tax must be a tax on the police principle and in proportion to the value that telephone or telegraph property bears to other city property it would be very useful, because the establishment of such a principle by the Supreme Court of the United States would render it impossible for any city or borough to tax at so much per pole, and as the cities and boroughs are trained to tax at so much per pole it would be a very important thing for telephone companies to know whether we could not on some legal basis established by the Supreme Court of the United States contest that effort of the boroughs.

The only other question I have to ask is that if there be any such principle established by the Supreme Court of the United States, whether there be within the knowledge of gentlemen present any principle established by the Supreme Courts of other states which could form a precedent towards establishing the law in Pennsylvania.

Mr. Gifford—The matter has never been brought before the courts of the state of Kentucky. I suppose there are always some persons in every legislature who from motives of patriotism or some other "ism" like to put a heavy tax on corporations. But we appeared before the committee on law and taxation in the Kentucky legislature and stated our case to them, and they decided to levy a state tax in this way: One-fourth of one per cent. upon our gross receipts in lieu of all other state taxes. While that is little more than the average rate that other people have to pay on their property we deemed it policy to consent to it, and it is the law. In the state of Kentucky machinery in operation is not taxed, and our assessors have considered that our central office system, our bells, telephone and transmitters come under the head of machinery, and they are not taxed. I have been in the habit of going to the assessor and asking him what he thought the thing was worth provided the patent was removed. I would say, "What would you give for those wires and poles around here?" He would say so many thousand dollars, and he taxed it that way, and we paid as we would on any other personal property at that rate. We also have a very reasonable business license. We are perfectly satisfied with it. It is about two and a half times what the average license is. The city license in the City of Louisville is based upon one dollar upon a thousand. At that rate our tax would be $125 or $150. They have assessed a license tax of $250 a year. We thought it would not pay to quarrel with the municipal authorities for $125, and we acquiesced in that. We anticipate no trouble from the tax question there; but nothing of the kind has ever been brought before the courts.

Mr. Durant—I presume that every possible question that could arise under the various laws authorizing taxation has been raised in the state of Missouri and passed upon, and as a rule all those things go to the Supreme Court. We pay a tax upon our personal property the same as any other city in the state. In addition to that the City of St. Louis is authorized by its charter to impose a license tax upon sundry callings, and it was a question whether they had that right to impose it on a telephone company. We concluded that it was very much better than a tax upon our poles, and when the matter was under consideration we concluded we preferred that. The result was that we pay an annual tax upon our gross receipts; it amounts to a considerable sum, and after 1890 it doubles.

Mr. Bailey—Do I understand the gentleman to say that he pays a tax on his gross receipts to the city government as well as the state?

Mr. Durant—No; we pay the tax on our gross receipts to the state. We pay the tax on our personal property—it would be to the county, but as a matter of fact the City of St. Louis is an independent locality by itself; it is not in any county. There is a county of St. Louis and a City of St. Louis, but they are independent organizations. The City of St. Louis used to be in the county of St. Louis, but by its special charter adopted some 12 years ago, it is independent of the county. We pay the tax on personal property to the collector of taxes. We pay the tax on the gross receipts within the confines of St. Louis city to the city treasury.

Mr. Drake—There are very simple matters in vogue in Iowa and Nebraska of taxation. In Nebraska the companies report their property direct to the state auditor. The statements are laid before the board of equalization. They assess the property and then assign to each county its proportion. The county authorities then collect the municipal and state taxes. In Iowa the state board of equalization fixes the assessments upon statements from the companies and levies the tax direct. The tax is paid to the state treasurer, and that is in lieu of all other taxes of every description. No other city or county authorities have any right to levy any tax on any telephone or telegraph property.

Mr. Durant—Are you quite sure that any city in Nebraska has a right to license?

Mr. Drake—In Nebraska they have a right to levy an occupation tax; that is a special prerogative bestowed upon municipalities; it is a tax upon the business, not upon the property.

Mr. Durant—Are those occupations specified in the charter of the City of Omaha?

Mr. Drake—Yes, sir.

Mr. Durant—And the telephone and telegraph companies are omitted from the list?

Mr. Drake—No; they are included in Nebraska. You, as an individual, may own a good piece of property on which you pay a special state and county tax. On that piece of property you are conducting a business. They will issue you a license to do a business in the town.

Mr. Durant—Why cannot they license you to do a telephone business in the City of Omaha?

Mr. Drake—They do not in the City of Omaha, but they do in many of the towns and cities.

Mr. Durant—Then, that license tax is in addition to the personal property tax?

Mr. Drake—Yes.

Mr. Mailey—I would like our president to give us some light on the tax question as to the states of Pennsylvania and Ohio.

Mr. Metzger—It seems to me that the tax question is a political one, and I cannot see how or in what way this association can affect the method or mode of taxation. In Pennsylvania, of course, we are taxed upon our gross receipts, and also upon the dividends. I think the tax is eight-tenths of one per cent. on our gross receipts, and then three mills upon every one per cent. of our dividends based upon our capital stock. In the smaller towns of Pennsylvania we are not taxed for poles. In the City of Pittsburgh proper we are taxed for business purposes. That is all the tax that we pay for business purposes, and, of course, we are taxed at the same rate as all other classes of business based upon the amount of sales or receipts. But there is no tax on poles, or wires, or telephones. In the state of Ohio they tax us on the poles. There they have a property tax. The tax is on the value of the plant, and they have sought, of late years, to tax us on the telephones. We have resisted this so far successfully, and we are taxed precisely the same as all other citizens are taxed. We think that we are entitled to pay our taxes just the same as the citizen who owns a house and lot, or in fact any other corporation.

In the state of Ohio we have no state tax. Of course, we exist there by comity between the states under the rule that a corporation chartered in one state may transact business in another state. We have another town in the western part of the state, called Newcastle. A member of the council there did not pay his bill, and we brought him up with a round turn and compelled him to pay his bill. In the tax ordinance he moved that the telephone companies pay $250 as a license tax. The electric light companies were taxed $125; the natural gas companies were taxed $125, and so on, depending upon the character of the business. We told the council plainly that we would resist the payment of that tax; that they had no right to discriminate; that if they taxed us the same as they taxed all other companies on the same volume of business, that we would pay; that we are not going to pay $250, when the natural gas companies whose revenues were 10 times greater than ours, paid only $125. What the result of that case will be, I don't know, but I am inclined to believe that the council will modify the action in that regard and tax us the same as they taxed the other companies. At least, if they do not, we shall resist it by all legal means that we have at our command.

The Chairman—I take it that Mr. Kerr wanted to get information as to the valuation of the telephone property as a basis for taxation as much as anything else. It might be interesting to get views of members from various parts of the country on that. In my experience I have had struggles with various assessors over their extravagant ideas of the values of poles and wires.

Mr. Gifford—If that is the subject, I would say that we make our returns based on the original cost of the plant, and from that we deduct 10 per cent. annually for depreciation. We make that return under oath, because we believe that is a fair statement of the actual value of the plant.

Mr. Bailey—I would inquire if in making those returns the president includes his corporation appliances or merely what we might term personal property and buildings. There was a law in Pennsylvania that a corporation was free from local taxation, and was only subject to the general taxation law of the state. In Pennsylvania, I think, the great bulk of the entire state government was carried on by taxation of corporations. Railroad and other corporations, gas companies and water companies, have fought that all the way through, and uniformly with success. About a year ago there was, as Mr. Kerr says, a law passed allowing cities to tax telephones and telephone companies at a certain rate. We have never made any resistance to what they attempted to do. The generality of cities have levied what they call a police tax—a police franchise, and rather than bring up the question, we have paid it cheerfully. Some of the smaller towns have

attempted the same thing. So far I have been able to throw them off the track by going and seeing the council—generally the council's attorneys, and arguing the question with them with the uniform results of having them withdraw all the claims. There is one case that I have in mind that, by agreement between our attorneys, was settled by a case stated; that is a question of law to be heard before a judge of the Court of Common Pleas; that has not come up yet.

Mr. Metzger—I would say, in regard to Mr. Bailey's remark, that there was an act passed in 1887, authorizing the creation of cities of the fourth, fifth, sixth and seventh class. That act gave express authority to councils to levy a tax on telephone companies in the language of the act. It is under the act that these councils are acting. They do not fix any rate, however; they leave it optional with the city council as to what it shall be.

The secretary's statistics were ordered printed, instead of being read, and the convention adjourned.

COURT OF PATENT APPEALS.

REPORT OF COMMITTEE ON THE JUDICIARY—HOUSE OF REPRESENTATIVES.

On September 12, the bill before Congress to create a Court of Patent Appeals, came up on a report submitted by Mr. Culbertson, of the judiciary committee. The report is as follows:—

[To accompany bill H. R. 9,084.]

The committee on the Judiciary, to whom was referred the bill (H. R. 9,084) to establish a court of patent appeals, have considered the same, and report it to the House and recommend its passage with amendments herewith submitted.

The court of patent appeals as provided for by the bill and amendments reported by the committee, consists of one chief justice and two associate justices, who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall hold office during good behavior, and receive a salary each of $6,000 per annum.

The associate justices shall take precedence according to the dates of their commission, or, when the date of the commissions may be the same, according to age.

The bill provides for the appointment of a clerk, deputy clerks, marshal, and reporter by the court. The fees of the clerk shall be the same as now allowed by law to the clerk of the Supreme Court, but shall not exceed $6,000 a year. The salary of the marshal is fixed at $2,000 per annum.

The pay of the reporter is not to exceed $2,500 annually, unless the number of reports required to be printed shall be increased by order of the court, in which case the salary or pay may be increased not exceeding $1,500 a year.

The court is required to hold one term annually at the seat of government, commencing on the second Monday in October, and may hold special or adjourned terms as the court may deem proper for the despatch of business.

The jurisdiction of the court as prescribed and defined in the bill is as follows:—

SEC. 14. The court of patent appeals of the United States shall have appellate jurisdiction in the cases hereafter specially provided for without regard to the sum in controversy.

1st. "From the courts of the United States having original jurisdiction of cases touching patents, copyrights, trade-marks, and labels, in all cases involving these subjects."

2. From the Commissioner of Patents in all cases touching the patentability of inventions, priority of invention among several claimants for patent upon the same invention, and in all cases of re-issue and the judicial practice of the Patent Office, also all cases touching the registration of trade-marks or labels and the rights of conflicting claimants therefor.

SEC. 15. From and after the passage of this act there shall be no appeal from the circuit courts of the United States or any territorial or district court or court of the District of Columbia, in cases touching patents, trade-marks, copyrights, or labels to the Supreme Court of the United States directly, but all such cases formerly appealable to the Supreme Court shall be heard on appeal by the court of patent appeals.

SEC. 16. There shall be a right of appeal from the court of patent appeals to the Supreme Court of the United States in all cases regardless of the amount in controversy; subject to the same regulations, however, as now exist with regard to appeals to the Supreme Court in causes of admiralty and the maritime jurisdiction, and to such further regulations as the Supreme Court of the United States may make.

SEC. 17. All cases touching patents, trade-marks, copyrights, or labels now pending before the Supreme Court of the United States awaiting trial shall be transferred to and heard by the court of patent appeals.

The expediency and propriety of, if not necessity for the establisement of, such a court as contemplated by this measure will not be questioned if proper consideration be given to the objects that will be attained by the passage of this bill.

Among the results reasonably expected to flow from the organization of a court of patent appeals, attention may be called to the following:—

(1) It would enable the public and patentees to determine the value and validity of patents without serious and vexatious delays, and thus promote the interests of all concerned.

(2) It will relieve the Supreme Court of much of the burden imposed upon it by this class of litigation.

(3) The practice in the Patent Office would become thoroughly fixed and understood and, as a consequence, the issue of worthless patents, in which unscrupulous persons deal to the injury of the public, would be greatly diminished, if not entirely suppressed.

(4) It would tend to simplifying the patent laws by con striction and settling questions of doubt which are often used by litigants for the purpose of injustice and oppression.

Without intending to present the reasons at length which induce your committee to arrive at the foregoing conclusions the following observations are submitted:—

The life of a patent, at most, is seventeen years, and if it is a valuable one, or intricate and radical, it usually requires one-fourth of that period to introduce it and secure its use by the public.

This, in part, results from the fact that manufacturers who must be relied upon to make and introduce new inventions are slow and reluctant to place in general use inventions which displace or render valueless articles in the production of which they are already engaged.

This is illustrated by experts, who say that to change from one style of gun to another requires from $1,000 to $2,000, and from six months to a year's time to make the model gun from which to make the dies, gauges, special tools, etc., and that to make these latter much time and money are required.

When ordinarily the financial life of a patent is abridged by the difficulties of placing the invention into general use, we can appreciate the importance of speedy decisions when it is infringed or when its validity is questioned.

Under the present condition of the business of the courts it requires, ordinarily, from two to three years to obtain a decision in the Circuit Court of the United States, and if appealed to the Supreme Court from three to four years are required to obtain a decision. It may be said that the same difficulty and delay attend the determination of all other questions involving the determination of property rights. While this is true, it should be borne in mind that this species or character of property differs from all other kinds of property. The duration of the owner's title is arbitrarily fixed by law. The period is short, for the most part, seventeen years.

The Constitution imposes upon Congress the duty of securing to authors and inventors, for a limited time, the exclusive right to their respective writings and inventions. It is submitted, respectfully, that this duty is very imperfectly discharged when, by the omission of Congress to provide proper means to determine questions arising out of patents, the life of a patent may be frittered away by the delays of the law.

As has been said, it requires from three to four years after a cause is filed in the Supreme Court to obtain a decision. This does not result from any fault of the judges. It is due solely to the fact that Congress has so broadened the appellate jurisdiction of the court as to overburden the physical capacity of the tribunal.

The original jurisdiction of the court, fortunately, is fixed by the Constitution, and Congress can not add to it or subtract from it, but the appellate jurisdiction of the court is subject to the power of Congress, and that authority has been exercised without proper regard to the physical capacity of the judges or the interests of litigants.

This condition ought not to be continued. It operates in a great many cases as a denial of justice, and every citizen of the United States is interested in bringing about a change.

It may be asked how this measure will contribute to that result? To that inquiry it may be answered that by the sixteenth section of the bill as quoted herein, it is provided that appeals from the court proposed to be established to the Supreme Court shall be subject to the same regulations as now exist with regard to appeals to the Supreme Court in causes of admiralty and maritime jurisdiction, and to such further regulations as the Supreme Court may make.

By reference to the act of 1875, relating to the practice in the courts of the United States in cases of admiralty upon appeals to the Supreme Court and the rule of the Supreme Court upon that subject, it will be observed that the Circuit Court is required to make a finding of facts and law, and the review of the judgments of the circuit courts by the Supreme Court in these cases is confined to questions of law only.

It follows that if a similar rule shall be applied to patent cases as the sixteenth section of the act provides, the Supreme Court in reviewing the judgments of the court proposed to be established will pass upon questions of law only, and thus from 15 to 20 per cent. of the time now consumed by the court in these cases in wading through voluminous records endeavoring to find the facts will be saved and profitably applied to the disposition of other business in the court.

It is difficult to perceive any good reason for requiring the Supreme Court to find the facts in patent cases and not in admiralty cases.

Upon the score of economy it is respectfully submitted that the expenses of this court will not exceed $30,000 per annum.

Such a sum of money bears no comparison to the amount that will be saved to the people of the United States by the speedy adjudication of questions arising out of patents. To this should be added also the incalculable advantage that will result to litigants

in the Supreme Court of the United States from the saving of time.

The income of the Patent Office for the fiscal year ending June 30, 1888, was $1,122,994.88 ; expenses, $953,730.14 ; leaving a surplus turned into the Treasury of the United States of $169,264.74, which, added to the previously credited surplus, makes a balance in the treasury to the credit of the patent fund of $3,337,666.65.

SEPTEMBER 12, 1888.—Committed to the Committee of the Whole House on the state of the Union and ordered to be printed.

AN ELECTRIC LIGHTING STATION A NUISANCE.

Supreme Court—Chambers.—New York.

PHILIP BRAENDER AGAINST THE HARLEM LIGHTING CO.

O'Brien, *J.*—The defendant sought to be enjoined is maintaining an electric lighting station adjoining plaintiff's houses on East 122d street, and though various grievances are alleged in the complaint, upon the trial only one was insisted upon, viz.; that the engines and machinery of defendant placed in the rear of the main building and working at night, jar plaintiff's buildings and create noises which are unusual and ill-timed. The station was erected and the machinery in the main building was running when plaintiff purchased the property. Subsequent thereto an extension was built in which a 400 h. p. engine was placed, which turns a cog wheel 16 feet in diameter.

The extension is shown to have been constructed in a good and substantial manner, and though complaint is made that the engine is driven by a cog wheel instead of belting, there is no dispute but that the engine itself was of the very best make and was built upon piers of solid brick.

It being shown that the buildings and engines were constructed in the best manner, the business itself carried on as well and carefully as such a business can be, and the neighborhood being such as not to make the establishment of a lighting station improper, it cannot be claimed to be a nuisance *per se*. Not being, therefore, a public or general nuisance, plaintiff, to succeed, must show some special injury to himself.

The two grounds of special injury sought to be proved were :—

First—Physical injury to the houses.

Secondly—Unusual disturbance and annoyance to tenants from noise and vibration caused by the engine and machinery in the extension.

These grounds, supported by evidence and showing permanent injury and continuing damage, would entitle plaintiff to an injunction.

I am, of course, familiar with decisions holding that the injury, annoyance or interference with the enjoyment of property must be substantial and real, the law not regarding trifles. The rule is well stated in Doellner *v.* Tynan, 38 How. 176 : "That if defendant is conducting his business in a convenient and proper part of the city, and in a careful and orderly manner, and it should not be interfered with merely because such business is incidentally annoying to the plaintiff * * * * or even render the enjoyment of his property uncomfortable."

This principle thus laid down is to be considered in connection with the rule laid down in McKeon *v.* Lee, 51 N. Y., 100 ; reported below in 4 Robertson).

This was an action wherein an injunction was granted against noise and vibration from an engine in a stone cutting establishment wherein the court says : "It may also be assumed for the purpose of testing plaintiff's right to relief that the defendant's business was lawful and publicly beneficial and conducted with every reasonable precaution as to the character of his building and machinery and mode of using them. This presents the naked question, whether the lawful character of the results of an occupation, trade or mechanical art, or the care with which it is carried on, can prevent any right of action by those whose enjoyment of life and property is disturbed by the mode or means of conducting such occupation."

Applying this test to the facts in this case as to the first ground—viz.: physical injury to buildings—I do not regard the evidence as proving such injury to be of a very substantial or permanent character. The buildings themselves have not been substantially injured, and the most that can be claimed is, that for purposes of immediate sale the causes complained of might injuriously affect the price.

A removal of the cause would operate a removal of the injury.

Upon the second ground—viz., unusual disturbance and annoyance to tenants—I regard the plaintiff upon the evidence as having a substantial grievance.

While the witnesses variously characterized the character and effect of the noise and motion of the machinery, whether we assume it to be only such a noise and vibration as is caused by a fire engine or ice wagon running past the houses as testified to by some, or as such a jarring and disturbance as to compel tenants to remove from the houses as testified to by others, either can hardly be regarded as trifling or harmless.

Regarding only the lesser of the two, while the passage of a fire engine or ice wagon occasionally would not interfere with the enjoyment of a house, the constant and uninterrupted rushing past of a fire engine or ice wagon might become an intolerable nuisance.

One of the controlling considerations, however, to my mind is the fact that before this large engine was placed in the extension the company conducted its business in an unobjectionable way, and the evils complained of did not then exist.

It would seem that for lack of space or to economize or concentrate power the company used the large engine and ran the machinery by a 16 foot cog wheel instead of having smaller engines and a wheel with belting. The motion of this large engine and cog wheel concededly produced the damage. It would appear as though the injury might be avoided. The 150 h. p. engine does the city's lighting, which is one-third of the entire business, and defendant had and has three of these smaller engines working with belting and direct attachment causing no trouble. It would seemingly, therefore, be but a matter either of convenience, expense or space to obviate the cause of the injury.

I know defendant claims that the substitution of smaller machines or of belting for the cog wheel, would require much more ground than they at present possess at 122d street. To accommodate their growing business they are erecting a new and enlarged station, now nearly completed, which will contain all their machinery. Their present station will then be entirely removed.

The defendant testified to the expenditure of about $200,000 for machinery, etc. It is at present supplying under contract with the city all the electric lights for the streets in Harlem, besides merchants and trades-people in that district, and the effect of an immediate injunction might prove ruinous to defendant, besides subjecting many persons using the lights and the city to much inconvenience. I am not unmindful, moreover, of the fact that much of the injury complained of, if suffered to be continued for a short time longer, can be compensated for in damages.

Taking into consideration the additional fact that the injury to defendant by the issuance of an injunction which would compel an immediate suspension of business would be greater than the benefit accruing to plaintiff, I am of opinion that while plaintiff should have judgment, the defendant should be allowed some time, to be fixed by the decree, to remove its plant before the judgment take effect.

Judgment accordingly. Filed September 17, 1888.

INTERNATIONAL TRAMWAY CONGRESS.

No very tangible results have been obtained by the International Tramway Congress, which opened here on Thursday last. The first matters discussed related to provident institutions, pensions, horses' rations, and to various kinds of tramway wheels. M. Michelet, chairman of the Brussels Tramway Company, read a paper on "Electric Traction," in which he stated that the difficulties experienced at first had now been removed by the accumulator plates being made larger and lighter, and at the same time stronger. The tramway company had kept accurate accounts of the expenses in connection with their accumulators ; a special account was kept for each battery of accumulators which was credited 10 centimes per kilometer run, and the various accounts were carefully compared. Each car ran from 100 to 110 kilometers per day, while each of the accumulators was used over about 40 kilometers per day. The company had found electric traction quite as dear as horse traction ; but improvements were pending which would bring about a reduction in the expenses. With regard to the question of working tramway systems, the director of the Vienna Steam Tramway considered that a tramway train should be composed of seven or eight cars, each carrying at least forty passengers ; that the surface of the platform should be reduced, and that the tickets should be delivered at stations, and not during the journey. A visit was paid to the accumulator charging station of the Brussels Tramway Company, and an inspection was also made of the Rowan steam cars used on the Brussels Schepdael line. The next meeting of the congress will be held at Milan in September, 1889, and the following one at Copenhagen in 1890.—*Industries.*

SUBMARINE CABLES.—CABLE CONCESSION IN HAWAII.

The Minister of the Interior has been authorized to enter into a contract with J. Sherman Bartholomew, residing in Honolulu, Hawaiian Islands, or with any other persons or corporation, for the construction and maintaining of a submarine telegraph cable or cables to connect the islands of the Hawaiian group from Hawaii to Kauai, as follows : From Hawaii to Maui, from Maui to Oahu, with a landing on Molokai, and from Oahu to Kauai, together with lines of land telegraph to connect the same with all or any points on the Hawaiian Islands. The contractors will have exclusive rights for submarine cables and connecting land lines for 10 years. It is provided that the cables shall be ready for use by July 1, 1889. The sum appropriated as a subsidy for the cable lines is $25,000.

LONG-DISTANCE TELEPHONY IN GERMANY.

The telephone lines Berlin-Dresden and Berlin-Breslau are completed. The distances are 105 and 200 miles respectively. The Dresden line was opened for traffic just recently, and the line may be used by telephone subscribers from their own instruments, and also by the general public making use of the call offices throughout the town or at the Bourse. The charge is 1s. for five minutes' conversation. The Breslau line is yet the subject of experiments by the post office, but will also shortly be opened for traffic.

ELECTRIC LIGHT AND POWER.

THE ATLANTIC COTTON MILLS, of Lawrence, Mass., have increased their Waterhouse arc light plant 77 arc lights, making 122 arc lights of the Waterhouse system in use at their mill.

THE PEOPLE'S ELECTRIC Co., of Easthampton, Mass., have ordered a combined arc and incandescent plant of the Waterhouse Electric and Manufacturing Co., of Hartford, Conn.

THE BRUSH ELECTRIC LIGHT CO'S station at Rochester, N. Y., is located at the foot of the Lower Genesee Falls, over 200 feet below top of the river bluff. The falls are over 300 feet wide and 94 feet high and are distant two and a half miles from the centre of the city.

The station is built of stone, three stories in height, 45 feet wide and 95 feet long; the penstock and wheel room are cut out of the solid rock. The building is fire-proof having iron joists, rafters and roofing. The dynamos are placed in the third story, in rows, and belt direct to turbine shafting in second story. The building is reached from the bluff by means of a large hydraulic elevator, the elevator well also contains all the wires for 26 circuits, and there is room for as many more.

The turbines are placed in heavy iron casings fastened to heavy iron beams bolted to the solid rock. The shafting runs at a speed of 800 revolutions, all journal bearings are fastened to iron bridge-trees, water is delivered to these turbines through three iron penstocks, six feet in diameter, each turbine is supplied through an independent elbow. At present 12 double 15 inch Lesner turbines are in use, and casings are placed for three more.

The dynamos in use are 25 No. 8 and 2 No. 7 Brush. The service now includes 1,150 arcs, 800 incandescent and 296 motors; power is furnished to two elevators, three laundries, 10 printing offices, three bakeries, telephone exchange, 61 tailor shops, 10 tea and coffee stores, and various other trades. The officers of the company are, G. E. Mumford, president; C. B. Griffith, secretary; Geo. A. Redman, superintendent.

.... * * * IT is a curious and suggestive fact that all moral forces and all moral questions find their final solution in the facts and laws of physical nature.—*Abram S. Hewitt.*

.... THE perfected alternating current motor is destined to play a most important and remarkable part in the development and commercial introduction of electric railways.—*Elias E. Ries.*

.... One scarcely knows which fact is the more astounding,—the distance at which the human voice can be reproduced, or the ridiculously simple apparatus that performs the reproduction.—*W. H. Preece.*

.... ANYONE looking at a common glow-worm must be struck with the fact that not by ordinary combustion, nor yet on the steam engine and dynamo principle, is that easy light produced. Very little waste radiation is there from phosphorescent things in general.—*Dr. Oliver Lodge.*

.... WE laugh a good deal at the rough and ready manner adopted on the other side of the Atlantic. The Americans, no doubt, are very ignorant of the difficulties that properly minded people would meet with; but it is a blissful ignorance where it is folly to be wise.—*Professor Ayrton.*

.... EVERYONE knows that combustion is not a pleasant or healthy mode of obtaining light; but everybody does not realize that neither is incandescence a satisfactory and unwasteful method, which is likely to be practiced for more than a few decades, or perhaps a century.—*Dr. Oliver Lodge.*

.... MANY calculations recall very forcibly the account given by John Phœnix (Lieut. Derby) of his experience in making a survey for the government of the distance from San Diego to the Mission Dolores. The method adopted was triangulation; but not having a full set of the proper instruments he used a three-legged stool instead. The instrument indicated a distance slightly in excess of seven miles; but for the purpose of correcting possible errors due to the personal equation of the observer and possible defects in the instrument, Phœnix stepped into a grocery, and taking an observation at the barkeeper through a glass, asked him what the distance was: The answer was that it was "about three mile and a half." Averaging this reply with the measurements obtained after the methods prescribed by science, Phœnix found the "true mean distance" to be five miles, three furlongs, and two and a half yards, and so reported to the government.—*Detroit Free Press.*

THE TELEPHONE.

MESSRS. MOURLON & Co., of Brussels, have received an order from the Portuguese government for all the material necessary for the erection of a telephone and telegraph line between Oporto and Lisbon, similar to those at present existing between Paris and Brussels, and Lyons and Marseilles.

PERSONAL MENTION.

MR. FRANK E. CLARK has resigned the treasurership of the Campbell Electrical Supply Co., Boston.

MR. W. A. GILES has accepted a position with the Sawyer-Man Electric Co., and will represent them as agent in the State of New York.

MANUFACTURING AND TRADE NOTES.

THE Clark standard cell, as improved mechanically by Mr. Durand Woodman, of Newark, who until recently has been employed in the testing dapartment of the United States Electric Lighting Co., possesses the merit of being portable, and unlike the ordinary Clark cell its usefulness is not destroyed by upsetting or by an accidental jar. A test made this summer at the Edison laboratory of two independent Clark cells made by Mr. Woodman, showed that after six months' use they agreed with each other within 0.00012 volt, or about 0.009 per cent. at the same temperature.

THE NEW ENGLAND GLASS WORKS of W. L. Libbey & Son Co., established in Boston in the year 1818, recently removed to Toledo, Ohio, owing to the advantages offered by that city as a centre for natural gas for fuel. The arrival of several hundred employés was the occasion of addresses of welcome, a parade and a banquet, to which the *Toledo Blade* devoted several columns of interesting matter. The factory, constructed under the supervision of Mr. E. D. Libbey, president of the company, is built in the latest and most approved manner, almost fire-proof, and with an especial view to the comfort and convenience of the workmen.

The well-wishes of the citizens of Toledo are echoed by the electrical fraternity, by whom the New England Glass Works have been so long and favorably known.

JAMES J. HICKS, 8, 9 and 10 Hatton Garden, London, E. C., sends us an illustrated and descriptive price list of new patent electrical instruments by G. L. Addenbrooke, embracing reflecting galvanometers, improved lamps and scales, Wheatstone bridges; together with keys and appliances for metrical apparatus. Mr. Hicks is the sole manufacturer of Mr. Addenbrooke's instruments.

MOORE BROTHERS, 108 Liberty street, New York, have issued their catalogue and price list No. 24, embracing a general line of telegraphic and other electrical instruments and supplies.

THE W. F. & JOHN BARNES Co., Rockford Ill., have recently sent out a new catalogue showing all the changes, improvements and additions made of late in their foot, hand and steam power machinery. Both amateurs and manufacturers will find much of interest in the catalogue of the Messrs. Barnes—embracing machines for a great variety of uses.

THE engines of the Ball Engine Co., Erie, Pa., have attracted much attention on the part of electric lighting companies, and many of their engines are now employed in that service. The Ball Co. has just issued a tasteful pamphlet circular, descriptive and illustrative of the special features of its engines, and containing other matters of interest to electric light engineers.

IT is very rarely that the patents of any one person comprise all the features necessary for the control of a system of great commercial utility, and we are glad to note that the several patents of Butz, Thompson, Bradford and others have been combined in the system of automatic temperature regulation recently placed on the market by the Consolidated Temperature Controlling Co., of Minneapolis, Minn., whose plan possesses the merit of being relatively simple in construction and convenient in use.

ELECTRIC STREET RAILWAYS IN AMERICA.

Now in Operation.

ABBREVIATIONS.—mi., miles of single track; g., gauge; lb., pounds rail per yard; m., electric motors; c., cars; m. c., motor-cars; h. p., horse-power; T., T-rail. Name of electric system used is in SMALL CAPITALS.

Allegheny, Pa.—Observatory Hill Pass. Ry. Co.—*Pr.*, Oliver P. Scaife; *Sec.*, Arthur Kennedy; *Tr.*, Jas. B. Scott; *Supt.*, Alexander Moffat; *Eng.*, ——; 3-7 mi.; g. 5-2½; 52 lb.; 4 m. c.; sta., 200 h. p.; overhead and conduit cond. BENTLEY-KNIGHT.

Ansonia, Conn.—Derby Horse Ry. Co.—*Pr.* Jno. B. Wallace; *Sec.* and *Treas.* Wm. J. Clark; *Supt.* Jas. D. Kennedy; 4 mi.; g. 4-8½; 45 lb.; 8 m. c.; 1 m.; sta. —— h. p.; overhead cond. THOMSON-HOUSTON.

Meriden, Conn.—New Horse R. R.—*Pr.*, T. J. Lathram; *Sec.* and *Tr.*, T. A. Lamb; 5 mi.; g. 4-8½; 35 lb.; 12 m. c.; overhead cond. DAFT.

Meriden, Conn.—Meriden Horse R.R. Co.—*Pr.*, Geo. R. Curtis; *Sec.* and *Tr.*, C. L. Rockwell; *Supt.*, D. Barker; 5 mi.; g. 4-8; 35 lb.; 12 m. c. DAFT.

Montgomery, Ala.—Capital City Elec. St. Ry. Co.—*Pr.* E. B. Joseph; *Supt.* G. B. Shellhorn; *Sec.*, W. F. Joseph; 7-9 mi.; g. 4; 42 lb.; 14 m. c.; sta. 150 h. p.; overhead cond. THOMSON-HOUSTON.

Pittsburgh, Pa.—Pitts., Knoxville & St. Clair St. Ry.—*Pr.*, Theo. Evans; *Tr.*, Henry Stamm; *Sec.*, J. W. Patterson; 2½ mi.; g. 5-2½; 43 lb.; 5 c.; 5 m.; steam-power; sta. 200 h. p.; overhead and conduit cond. SPRAGUE.

Port Huron, Mich.—Port Huron Elect. Ry.—*Pr.*, Wm. P. Botsford; *Sec.* and *Supt.*, Jas. H. Talbot; 2.75 mi.; g. 4-8½; 27 lb.; 3 m. c.; sta. 55 h. p.; overhead cond. THOMSON-HOUSTON.

Richmond, Va.—The Richmond Union Pass. Ry. Co.—*Pr.*, W. R. Trigg; *Sec.* and *Tr.*, Andred Pizzini; *G. M.*; G. A. Burt; *Eng.* A. L. Johnston; 13 mi.; g. 4-8½; 45 lb.; 40 m. c.; sta. 400 h. p.; overhead cond. SPRAGUE.

Salem, Mass.—Naumkeag St. Ry. Co.—*Pr.*, C. Odell; *Tr.*, H. Wheatland; *Sec.*, J. F. Hickey; *Supt.*, W. B. Furgurson; 1½ mi. Willows branch; g. 4-8½; 6 m. c.; 35 lb.; 80 p. c.; sta. 100 h. p.; 6 m. c.; overhead cond. SPRAGUE.

San Diego, Cal.—San Diego St. Ry. Co.—*Pr.*, Dr. Granchenor; *V. P.*, Juan Franceeco; 9 mi.; 4 m. c.; overhead cond. HENRY.

San Jose, Cal.—San Jose & Santa Clara R. R. Co.—*Pr.*, S. A. Bishop; *Sec.*, E. Rosenthall; *Tr.*, J. Rich; *Supt.*, W. Fitts; 10 mi.; g. 3; 6 m. c.; sta. 130 h. p; conduit cond. FISCHER.

St. Catherines, Ont.—St. Catherine's, Merritton & Thorold St. Ry. Co.—*Pr.*, E. A. Smyth; *Sec.*, A. P. Friesman; *Supt.*, R. McMaugh; *Eng.*, W. S. Smith; 5.75 mi.; g. 4-8½; 30 lb.; 4c.; 12 m. c.; sta. 400 h. p. (water power); overhead cond. VAN DEPOELE.

St. Joseph, Mo.—St. Joseph Union Pass. Ry. Co.—*Pr.*, Seymour Jenkins; *Sec.* and *Tr.*, A. Steinacker; *Supt.*, Chas. Wilson; 9½ mi.; g. 4-8½; 35 lb.; 8 m. c.; 13 m. c.; overhead cond. SPRAGUE.

Scranton, Pa.—Scr. Suburban Ry. Co.—*Pr.*, Edw. B. Sturges; *Sec.*, G. Sanderson; *Tr.*, T. F. Torrey; *Supt.* and *G. M.*, B. T. Killam; *Eng.*, J. Nazel; 4.5 mi.; g. 4-8½; 35, 40 and 52 lb.; 14 m. c.; sta. 300 h. p.; overhead cond. THOMSON-HOUSTON.

Syracuse, N. Y.—Third Ward Ry. Co.—*Pr.*, W. B. Cogswell; *Sec.* and *Tr.*, W. S. Wales; 4 mi.; g. 4-8½; 35-50 lb.; 8 m. c.; overhead cond. THOMSON-HOUSTON.

Washington, D. C.—Eckington & Soldier's Home Ry. Co.—Overhead cond. THOMSON-HOUSTON.

Wheeling, W. Va.—Wheeling Ry. Co.—*Pr.*, Jno. Spiedel; *Sec.*, Jno. M. Sweeney; 5.25 mi.; g. 5-2; 45 lb.; 12 m. c.; sta. 240 h. p.; overhead cond. THOMSON-HOUSTON.

Wilkesbarre, Pa.—Wilkesbarre & Suburban St. Ry. Co.—*Pr.*, H. H. Sen; *Sec.*, W. E. Shupp; *Tr.*, C. Walter; *Supt.*, A. C. Robertson; 3-6 mi.; g. 5-2; 50 lb.; 7 m. c.; sta. 120 h. p.; overhead cond. SPRAGUE.

Wilmington, Del.—Wilmington City Ry. Co.—*Pr.*, W. Canby; *Sec.* and *Tr.* J. F. Miller; *Supt.*, W. H. Burnett; 6½ mi.; g. 5-2; 47 lb.; 13 m. c.; overhead cond. SPRAGUE.

Windsor, Ont.—Windsor Elect. St. Ry. Co.—*Pr.*, W. M. Boomer; *Sec.*, A. H Joseph; *Supt.* W. C. Turner; *G. M.*, P. C. Ponting; 1.5 mi.; g. 3-6; 25 lb.; 1 c.; 1 m. c.; sta. 20 h. p.; overhead cond. VAN DEPOELE.

Woonsocket, R. I.—Woonsocket, St. Ry. Co.—*Pr.*, Horace H. Jenckes; *Sec.* and *Eng.*, Willard Kent; 1 mi.; g. 4-8½; 25 and 50 lb T; 1 m. c.; sta. 1,000 h. p.; overhead cond. THOMSON-HOUSTON.

Constructing or Under Contract.

Akron, Ohio.—Akron Electric Ry. Co. 6½ mi.; 12 m. c.; overhead cond SPRAGUE.

Asheville, N. C.—Asheville St. Ry.—3 miles; 4 m. c.; overhead cond. SPRAGUE.

Attleboro, Mass.—Att., N. Attleboro & Wrentham St. Ry. Co.—*Pr.*, H. G. Bacon; *Tr.*, J. E. Draper; *G. M.*, H. M. Daggert, Jr.; 6 mi.; g. —— lb.; —— c.; —— m.; sta. —— h. p.; overhead cond.

Bangor, Me.—

Boston, Mass.—West End Ry. Co., Brookline branch.—12 mi.; 20 m. c.; overhead cond. SPRAGUE.

Buffalo, N. Y.—Citizen's Elect. Ry. Co.—*Pr.*, A. P. Wright; *Sec.*, F. F. Fargo.

Chattanooga, Tenn.—Chat. Elect. St. Ry. Co.—*Pr.*, C. A. Lyerly; *Sec.*, C. E. Scott; *Tr.*, C. V. Brown; *G. M.*, E. Scott; 4 mi.; g. 4-8½; 25 lb.

Cleveland, O.—East Cleveland R. R. Co.—*Pr.*, A. Everett; *Sec.* and *Tr.*, H. A. Everett; *Supt.*, E. Duty; 23½ mi.; g. 4-8½; 45 lb.; 16 m. c.; overhead cond. SPRAGUE.

Danville, Va.—Danville St. C. Co.—*Pr.*, T. B. Fitzgerald; *Sec.* and *Tr.*, P. R. Jones; *Supt.*, M. W. Buckley; 1.6 mi.; g. 4-8½; 38 lb.; overhead cond. THOMSON-HOUSTON.

Des Moines, Iowa.—Capital City St. Ry. Co.—*Pr.*, G. Van Ginkel; *Sec.*, H. E. Teachout; *Tr.*, J. Weber; 7 mi.; g. 4-8½; 45 lb.; 8 m. c.; overhead cond THOMSON-HOUSTON.

Elsinore, Cal.—Elsinore Lake Shore Elect. Ry. Co.—*Pr.*, D. G. Dexter; *Sec* and *Manager*, H. L. Courad; *Tr.*, F. H. Heald.

Erie, Pa.—Erie City Pass. R. R. Co.—*Pr.*, W. W. Reed; *Sec.*, J. L. Sternberg; *Supt.*, Jacob Borst.; 8½ mi.; g. 4-8½; 20 m. c.; overhead cond. SPRAGUE.

Flushing, N. Y.—Flushing & College Point St. R. R.—*Pr.*, J. Dykes; *Sec.*, Charles Frey; *Tr.*, Henry Clement; g. 4-8½; 45 lb.; 1 mi.; storage bats.

Hudson, N. Y.—Hudson Electric Ry. Co.—*Pr.*, H. McGonigle; *Sec.*, E. J. Hodge; *Tr.*, S. D. Loke; 3 mi.; g. 4-8½; 30-50 lb.; 4 m. c.; overhead cond. THOMSON-HOUSTON.

Lafayette, Ind.—Lafayette St. Ry.—*Pr.*, G. E. C. Johnson; *Sec.*, T. J. Levering; 2¼ m.; g. 4-8½; 27-35-52 lb.; 9 m. c.; 9 Sprague cars. SPRAGUE.

Lakeside, O.—3 mi.; 2 c.; overhead cond.

Lincoln, Neb.—Lincoln Cable Ry. Co.—*Pr.*, J. H. Ames; *Sec.*, L. Coon; 5 mi. g. 4-8½; 56 lb.; 10 m. c.; storage bats.

Louisville, Ky.—Central Pass. R. R. Co.—*Pr.*, B. du Pont; *Sec.*, J. C. Donigan; —— mi; g. 5.

Lynn, Mass.—Lynn & Boston Ry. Co.—*Pr.*, A. F. Breed; *Tr.* and *Clerk*, E F. Oliver; *Supt.*, L. C. Foster; g. 4-8½; overhead cond. THOMSON-HOUSTON

Manchester, Va.—Richmond & Manchester Ry. Co.—*Pr.*, J. E. Taylor; *V Pres.*, J. Bryan; *Sec.* and *Treas.*, Jackson Brandt; *Supt.* B. R. Selden; 3½ mi.; g. 4-8½; 38 lb.; 10 m. c., 10 Sprague cars; overhead cond. SPRAGUE.

Minneapolis, Minn.—Minneapolis St. Ry. Co.—*Pr.*, Thos. Lowry; *Sec.* and *G. M.*, J. E. Rugg; *Treas.*, M. B. Koon; *Supt.*, D. W. Sharp; *Eng.*, E. T. Abbott; 69½ mi.; g. 3-6; 27-35-45 lb.; 8 m. c.; overhead cond. SPRAGUE.

Newton, Mass.—Newton St. Ry. Co.—*Pr.*, H. B. Parker; *V. P.*, Joseph W. Stover; *Sec.* and *Treas.*, H. C. Pratt (office, Newtonville, Mass); 6 mi.; g, 4-8½; 52 lb.

New York, N. Y.—N. Y. & Harlem (Fourth Avenue) R. R. Co.—*Pr.*, C. Vanderbilt; *Sec.* and *Treas.*, E. V. W. Rossiter; *Supt.*, Alfred Skitt; 18½ mi.; g. 4-8½; 60 and 75 lb.; 10 m. c.; storage bats. JULIEN.

New York, N. Y.—North & East River Ry. Co.—*Pr.*, W. W. Laman; 1 mi.; g 4-8½; cond. conductor. BENTLEY-KNIGHT.

North Adams, Mass.—Hoosac Valley St. Ry.—*Pr.*, W. B. Baldwin; *Sec.*, S P. Thayer; *M.*, H. A. Fitzsimons; 5 mi.; g. 4-8½; 40 lb.; 5 m. c.; overhead cond. THOMSON-HOUSTON.

Omaha, Neb.—Omaha Motor Ry. Co.—*Pr.*, Dr. S. D. Mercer; *Sec.*, J. T. Hertzman; *Treas.*, S. S. Curtis; 5 mi.; g. 4-8½; 56 lb.; 20 m. c.; sta. 250 h. p.; over head cond. THOMSON-HOUSTON.

Ontario, Cal.—Ontario & San Antonio Heights Ry. Co.—*Pr.*, Chas. Frankish *Sec.* and *Treas.*, D. McFarland; 8 mi.; g. 4-8½; 34 lb.; 4 c.; 3 m.; overhead cond. DAFT.

Philadelphia, Pa.—Lehigh Ave. Ry. Co.—*Pr.*, J. T. Banting; *Sec.* and *Treas.*, J. McK. Barron; 6 mi.; g. 5-2½; 47 lb.; storage.

Port Chester, N. Y.—P. C. & Rye Beach St. Ry. Co.—*Pr.*, F. H. Skeele; *Sec.*, E. H. Cook; *Tr.*, C. D. Newton; *V. P.*, M. Dillon; *Supt.*, T. M. Burt; 3 mi.; g. 4-8½; 38 lb.; 5 m. c.; overhead cond. DAFT.

Reading, Pa.—Reading & Black Bear Ry.—1½ miles; 2 m. c.; overhead cond SPRAGUE.

Revere, Mass.—Lynn & Boston R. R.—Ocean Ave. line; overhead cond. THOMSON-HOUSTON.

Richmond, Va.—Richmond City Ry. Co.—*Pr.*, J. L. Schoolcraft; *Treas.*, Walter Kidd; *M.*, C. M. Bolton; *Supt.*, Charles Selden; 7½ mi.; g. 4-8½; 30-40 lb.; 50 m. c.; overhead cond. SPRAGUE.

Rochester, N. Y.—Rochester Elect. Ry.—*Pr.*, A. T. Soule; *Sec.*, J. B. Perkins; 9 mi.; 4-8½; 40 lb.; 20 c.; 8 m.

St. Joseph, Mo.—Wyatt Park Ry. Co.—*Pr.*, J. M. Huffman; *Sec.*, I. R. Williams; capital, $300,000; 5 mi.; g. 4-8½; 10 m. c.; overhead cond.; 8 Sprague cars. SPRAGUE.

St. Louis, Mo.—Lindell Ry. Co.—*Pr.* J. H. Lightner; *Supt.*, G. W. Baumhoff; *Eng.*, E. J. Bagnall; —— mi.; g. 4-10; 65 lb.; 1 m. c.; 2 m.; 3 p. c.; storage bats.

Sacramento, Cal.—Sac. Elect. Ry. Co. The Central Street Railway Co.—*Pr.*, L. L. Lewis; *Sec.*, E. K. Alsip; *Tr.*, F. Miller; *Supt.*, J. B. Austin; *Eng.*, ———; 13 mi.; g., 4-8½. Cars to be supplied by Electric Car Co, of America, Philadelphia.

Sault Ste. Marie, Mich.—S. St. M. St. Ry. Co.—*Pr.*, E. M. Lacy; *Sec.*, F. Ryan; *G. M.*, L. G. Cody; 2 mi. FISHER.

Sandusky, O.—Sandusky St. Ry. Co.—*Pr.*, Chas. V. Olds; *Sec.* and *Treas.*, A. C. Moss; *Supt.*, Clark Rude; 4 mi.; g. 4-8½; 32 lb.; 6 m. c.; overhead cond.; 6 Sprague cars. SPRAGUE.

Scranton, Pa.—The Nayaug Crosstown R. R. Co.—*Pr.*, E. B. Sturges; *Sec.*, A. Frothingham; *Tr.*, G. A. Jessup; *Supt.* and *Eng.*, T. Gibbs; 1-5 mi.; 4-8½; 52 lb.; 2 m. c.; steam power; sta. 250 h. p.; overhead cond. VAN DEPOELE.

Scranton, Pa.—The People's St. Ry.—*Pr.*, W. Matthews; *Sec.* and *Tr.*, H. E. Hayd; *Supt.*, F. Pearce; 10 mi.; g. 4-8½; 20 m. c.; overhead cond. SPRAGUE.

Seattle, Wash. Ter.—

South St. Paul, Minn.—So. St. Paul Rapid Transit Co.—*Pr.*, A. E. Clark; *Sec.* and *G. M.*, J. H. Lawrence; (Enos elevated railway); 8 mi. 40 and 56 lb.; 10 m. c.; track conductors. DAFT.

Springfield, Mo.—2 mi. FISHER.

Steubenville, O.—Steubenville Electric Ry. Co.—2¾ mi.; g. 4-8½; 40 lb.; 7% grade: 10 m. c.; overhead cond. SPRAGUE.

Sunbury, Pa.—Sun. & Northumberland St. Ry. Co.—*Pr.*, H. E. Davis; *Sec.*, L. H. Kase; *Tr.*, S. P. Wolverton; 3 mi.; 4 c.; overhead cond.

Syracuse, N. Y.—Third Ward Ry. Co.—*Pr.*, Wm. B. Cogswell; *Sec.* and *Treas.*, W. S. Wales; *G. M.*, H. McGonegal; 4 mi.; g. 4-8½; 8 m. c.; 4 p. c.; steam power; sta. 250 h. p.; overhead cond. THOMSON-HOUSTON.

Wichita, Kas.—Wichita & Suburban Ry. Co.—*Pr.*, G. C. Strong; *Supt.*, O. J. Chapman; (contract for 2 miles); 7 mi.; 30-40 lb.; 3 m. c.; overhead cond. THOMSON-HOUSTON.

Worcester, Mass.—Worc. & Shrewsbury—(To be changed from steam to electricity); 2.7 mi.; g. 3; overhead cond. DAFT.

RECAPITULATION.

Roads Now in Operation,	**43**
Roads Constructing or Under Contract,	**48**

Notes.

THE THOMSON-HOUSTON Co. will begin at once the construction of a line for the West End R. R. Co., Boston, from Harvard square, Cambridge, to Arlington, to be operated by the overhead system so called. Cars are to be in operation within 60 days, and as soon after the completion of this section as possible, work will be begun on a line to enter Boston as far as Bowdoin square.

THE SPRAGUE COMPANY, as will be seen in the above lists, have followed up their success at Richmond, Va., by taking a number of contracts for the equipment of electric street railways in various parts of the country.

IN NEW YORK STATE the Third Ward Railway Co., of Syracuse, have contracted with the Thomson-Houston company for the complete equipment of four miles of road with the overhead system and the construction of eight motor cars. This company contemplates extensive additions, and there is no doubt but what the city will soon possess one of the finest electric roads in the United States. This road will be in operation the first of October, and nearly all the work has already been completed.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From August 21 to September 18, 1888 (inclusive).

Alarms and Signals:—*Electric Signaling*, C. Ader, 388,008, August 21. *Circuit-Closer for Call Systems*, C. E. Dey, 388,344. *Fire-Telegraph*, J. H Guest, 388,357. *Automatic Fire-Telegraph*, 388,358. *Circuit Changing Device for Burglar Alarms*, F. H. Nutter, 388,488. *Thermal Circuit-Closer for Fire-Alarms*, H. S. Petit and H. S. Bresson, 388,505. *Electric Fire-Alarm Signal Box*, S. A. Chase, 388,631, August 28. *Electric Bell*, M. G. Crane, 388,836. *Electric Annunciator*, C. H. Crockett and C. C. Allen, 388,837. *Electric Signal*, H. T. Hill, 388,869. *Magnetic Annunciator*, W. Humans, 388,876, *Electro-Magnetic Bell*, same, 389,080. *Device for Actuating Street or Station Indicators*, W. A. Turner, 389,122, September 4. *Electro-Mechanical Gong*, J. P. Tirrell, 389,423, September 11. *Fire-Alarm System*, T. G. Turner, 389,678. *Telegraphic Call for Messengers, &c.*, B. Dubinski, 389,839, September 18.

Clocks:—*Electric Motor for Self-Winding Clocks*, F. W. Brainerd, 388,622, August 28.

Conductors, Insulators, Supports and Systems:—*Underground Electric Conduit*, E. H. Phipps, 388,442. *Electrical Conductor*, W. A. Conner, 388,477. *Suspending Overhead Electric Wires*, A. E. Harris, 388,487, August 28. *Electric Conductors and Process of Uniting the Same*, C. McIntire, 389,314, September 11.

Distribution:—*Electrical Distribution by Secondary Batteries*, T. P. Conant, 389,638. *Means for Distributing Electric Energy*, S. Z. Ferranti, 389,795 and 389,838, September 18.

Dynamos and Motors:—*Dynamo-Electric Machine*, M. Waddell, 388,093, August 21. *Electric Motor*, J. T. Van Gestel, 388,512. *Commutator for Dynamo-Electric Machines*, same, 388,513. *Electric Motor*, J. Batley, 388,753, August 28. *Magneto-Electric Machine*, W. Humans, 388,877. *Dynamo-Electric Machine*, A. L. Riker, 389,011. *Regulator for Dynamo-Electric Machines*, A. G. Waterhouse, 389,029. *Regulation of Dynamo-Electric Machines*, same, 389,030. *Commutator for Electric Generators*, O. Zech, 389,184, September 4. *Electric Motor*, H. A. Chase, 389,197. *Electric Motor*, A. E. Eastwick, 389,207. *Switch for Electric Motors*, G. D. Shepardson, 389,254. *Alternate-Current Electric Motor*, W. A. Anthony, D. C. Jackson and H. J. Ryan, 389,352, September 11. *Armature-Winding for Dynamo-Electric Machines*, W. H. Knight, 389,658. *Conductor for Dynamo-Electric Machines*, E. F. H. H. Lauckert, 389,752. *Dynamo-Electric Machine*, T. H. Hicks, 389,812, September 18.

Galvanic Batteries:—*Galvanic Battery*, H. Cassard, 388,181. *Battery Zinc*, B. Scarles, 388,312, August 21. *Galvanic Battery*, A. V. Meserole, 388,430. *Process of Making Battery-Zincs*, R. L. EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 11 *Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. VII. NEW YORK, NOVEMBER, 1888. No. 83.

SOME REMARKABLE VIEWS IN ELECTRICITY.

PERHAPS the old time "lightning-rod man" with his hollow conductors, will soon be found to have been nearer the truth than the incredulous electricians who reviled his notions as to proper conductors for the safe conveyance to earth of violent electric discharges. This thought, along with others of more significance closely related to it, comes to mind on the perusal of Professor Lodge's abstract of the electrical papers read at the September meeting of the British Association for the Advancement of Science, which we reprint in other columns of this issue.

At the outset Professor Lodge indulges in a little suave merriment, as several other observers have done, at the expense of those members of the Association who may be called engineers rather than instigators or theorists; but, his brief fun over, settles down to a most interesting and suggestive account of the electrical papers in Section A (Mathematical and Physical Science), at the Bath meeting.

The practical or engineer class of electricians will find much material for reflection and incentive to experiment in the abstracts given of several papers relating to the general question of electric conduction, and in Professor Lodge's comments upon them, taken in connection with the "Lightning Rod Discussion," the general outcome of which latter, as summarized by Professor Lodge, we print in parallel columns.

Very special and practical interest attaches to the views of Sir William Thomson, Professor Lodge, and others, in respect to the conduction of oscillatory currents, either rapidly alternating or rapidly fluctuating. Their experiments lead to the conclusion, which they express with much confidence, that the passage of such currents is confined more or less closely to the surface of a conductor, the depth of penetration depending upon the rate of alternation or change; the lower the rate the deeper the penetration, till in a steady current it reaches the entire mass.

This view is of the utmost significance in respect to alternate current distribution. Indeed, Sir William Thomson, assuming 150 complete alternations per second to be the rate now employed in practice, reckons the depth to which the currents penetrate the conductors at three millimeters, and thinks that the conductors should be tubes or flat bars.

This theory of conduction, of the highest importance to the electrical engineer if verified in practice, is closely related to the more recent views on the nature of electricity and its relation to the all but demonstrated ether, or universal medium or substance, and is particularly interesting in connection with the speculations and theories presented by Professor Lodge in his series of articles in *Nature*, on "Modern Views of Electricity."

A HEROINE.

UNCONSCIOUS heroism, in the performance of simple duty in the face of imminent peril on the part of one in humble position, stirs the heart of the beholder, if not the imagination, more deeply than the great deeds of great men done with the eyes of all the world upon them.

Miss Mamie Davis, of Jacksonville, Florida, an operator in the telephone exchange there, held to her post and her work when left entirely alone for a time during the yellow fever epidemic. We have by chance had the privilege of seeing a letter from one of her superiors, from which the following is an extract:—

"Mamie Davis has been sick to-day and has not been to the office, so I had to do operating and a little of everything; I do not think Mamie has any symptoms of the fever, but it is dangerous to get sick now. She had a very hard cold yesterday and complained of feeling tired. I told her to go home and I would do the operating, but she refused. Her brother said this morning that she had no fever, and would be back to-morrow.

"There is no doubt that if it had not been for her, the exchange would have been closed. At one time we were all down (including Manning) and for one day she ran everything by herself. * * * For some time she had been alone with Manning working from six in the morning till night, and eating her dinner at the board. She does not take any special credit to herself but says it was very sad and lonely, the only company being the calls, and most of them for doctors, undertakers and ambulances, and she was constantly expecting to hear that some one of us was dead. She and her little brother, a messenger boy for the telegraph company, support her mother and themselves. Her mother did plain sewing and rented rooms before the fever broke out, but since has not been able to earn anything. I sincerely hope she is not going to have the fever."

No word of ours could add a touch to the picture thus presented to the reader's mind of this heroic girl alone in the exchange, her luncheon in one hand, switch plugs and cords in the other, keeping up communication in the fever and panic-stricken city.

At the Twenty-third Annual Meeting of the American Society of Mechanical Engineers, held at Scranton, Pa., October 15–20, Mr. C. J. H. Woodbury, vice-president of the society, read a paper on Electric Welding, presenting a clear and interesting account of its principles, apparatus, process and applications, with some remarks on the strength of electric welds. The paper was supplemented by tables comprising the official record of tests made on the Emery testing machine at the United States Arsenal, Watertown, Mass., by the Ordnance Department, U. S. A. The tables include the results of tests of 78 welds. The metals were iron, steel, copper, brass and german silver; the bars being of a variety of sizes from one-quarter inch to four inches in diameter. The tables give the tensile strength and the position of the fracture. The fractures are reported as follows:—23 "at weld," 2 "at enlarged section of weld"; 4 "at or near weld"; 33 at varying distances from weld (that is quite clear of the weld or the enlarged portion); 16 are not reported.

Commenting on the results already attained in this new application of electricity, Mr. Woodbury says:—

"There is no reason why such a weld should be stronger than the rest of the bar, but if averaging of equal strength some of the breaks would occur at the weld."

"It will be readily understood, however, that as this process accomplishes many things hitherto impossible, aside from any question of ultimate strength, it is fitted for applications in many constructions where it saves labor and time; provided only that the joints be in all cases sufficiently good for the purpose for which the article is designed. A large field thus opens up in the execution of ornamental design in metal work, where it will supplant screws, rivets or solder for fastenings, and in other evident applications."

The announcement in regard to the testing of electrical instruments and apparatus in the physical laboratory of the Johns Hopkins' University, under the direction of Dr. Rowland, with Dr. Duncan and Dr. Liebig in charge of the tests, must prove of great interest to investigators, students and practical electricians. American electricians and the capitalists interested in the financial results of their work are becoming more and more appreciative of the value—not to say the imperative need—of accuracy in determining the quantitative elements involved in their apparatus and operations. Every facility for precise measurement means the possibility of saving money by cutting off wasteful expenditure.

In the unworldly precincts of scientific research and study, accuracy is prized for its own sake merely; and, from the scale of charges for tests promulgated in the circular of the Johns Hopkins' University, it may fairly be inferred that Drs. Rowland, Duncan and Liebig are far more greatly concerned for the promotion of trustworthy electrical work than for the enhancement of the University's revenue.

The Boston *Evening Transcript* points out an anticipation of the phonograph, by Jean Ingelow, who, according to an English writer, gave the world the idea of the invention in a story first published in "*Good Words*" (or one of the magazines bearing, Strahan's imprint) in 1872, and reprinted in the "Little Warderhorn." From a fairy tale called "Nineteen Hundred and Seventy-Two" the *Transcript* prints the following extract:—

He began to describe what was evidently some great invention in acoustics, which he said (confusing his century with mine), "you are going to find out very shortly. * * * You know something of the simple beginnings of photography?" I replied that I did. "Photography," he remarked, "presents a visible image; cannot you imagine something analogous to it which might present an audible image? The difference is really that the whole of a photograph is always present to the eye, but the acousticgraph only in successive portions. The song was sung and the symphony played at first, and it recorded them, and gave them out in one simultaneous horrible crash; then when we had once got them fixed, science soon managed, as it were, to sketch the image; and now we can elongate it as much as we please." "This is very queer," I exclaimed; "do you mean to tell me these notes and these voices are only the ghosts of sounds?" "Not in any other sense," he answered, "than you might call a photograph the ghost of sight."

A telegram from Pittsburgh, October 30th, printed in the New York papers of 31st, announces that the Westinghouse Electric Co. "has been awarded the contract for a plant to light the City of London, England. It will be the largest plant in the world." This contract is with the Metropolitan Electric Supply Co., Limited whose prospectus was noticed in these columns in September last; a company proposing to engage in supplying electric light from central stations on a large and comprehensive scale in the English capital. The present order is understood to be for a 25,000 lamp outfit.

It is a matter of congratulation that American enterprise has succeeded in meeting and vanquishing sharp and persistent home competition in supplying London with an electric plant of such magnitude as that to be furnished by the Westinghouse company.

His Honor, the present Mayor of New York, never misses an opportunity to put himself on record in respect to the overhead wire question. We have several times directed the attention of our readers to his felicitous and humorous sallies in the Board of Electrical Control. The following episode is reported as occurring at a meeting of the Board of Estimate and Apportionment, a few days ago:—

General Newton said it would cost $4.00 each to remove the 40,000 telegraph poles to be removed next year.

"Well, gentlemen," Mayor Hewitt said, "will any of you move an appropriation of $160,000 for that purpose?"

There was no response.

"Then, gentlemen," said the mayor, blandly, "I hope the reporters will note the fact, you leave me powerless to remove the poles."

"Deutscher Fernsprechvielfachklappenschrank" is the neat little trade name of the multiple switch-board proposed for use in Germany by a distinguished continental scientist.

If "An Old Subscriber," who wrote us September 5, will kindly send us his address, we will take pleasure in responding to his enquiry.

OBSERVATIONS.

A FEW days ago a minister of the gospel, by way of an illustration, spoke of the "*potentialities of the church for good.*"

What he meant was simply the "possibilities, etc." Isn't it one of the dearest prerogatives, and proclivities, of the natural man to use a big word which means something, in preference to a little word which means the same thing; especially when we have reason to believe that our hearers may possibly find their understanding of our big word a little shadowy? It is immensely gratifying to be able to fling out a word that is rather darkly significant.

And this little human weakness must be held accountable for the glibness with which the unthinking, as well as the thinking, electrician talks learnedly about "potentials" and "capacities," too frequently, we fear, without a very clear idea of what they really are.

As for the word "potential;" of course, for the most part, our practical electricians have a clear and accurate idea of its meaning and scope, as being the representative of possible power; of wound-up energy, so to speak; and when applied to electricity, as standing for its power and readiness to do work; but it is a good word for the charlatan, and he works it. "Potential," as used ordinarily, and representing the *difference* of potential" between the electrical condition of a particular body or point and the earth, or between two bodies or points, was introduced into electrical terminology in the year 1828; its first appearance being in a book entitled, "An Essay on the Application of Mathematical Analysis to the Theories of Electricity and Magnetism."

For a long time it hung fire, but when used, was employed as being an elegant and sonorous word, by a few writers, and chiefly as a synonym for tension and electromotive force. It stands very well for the first, but differs from the last, as Mr. Hering has well shown in his book.

. . .

GEORGE GREEN, the writer of the book referred to above, is very little known now-a-days; he is not often mentioned, and when he is spoken of, is very likely to be miscalled. Professor Rowland referred to him in his opening address at the Electrical Conference in 1884, and called him *James* Green; perhaps confounding him for the moment with the Philadelphia worthy of that name, who wrote, in 1827, a work on Electro Magnetism.

George Green was born in Nottingham, England, July 14, 1793; and died March 31, 1841, at Swinton. Latimer Clark, speaking of his book, says "it is one of the most important works ever written on electricity;" and Fleeming Jenkin gives us a dissolving view of him in the opening lines of the second chapter of his book "Electricity and Magnetism."

. .

JACKSON, Miss., sends a despatch dated Sept. 25, to the Associated Press, relating to the yellow fever scare; one of its paragraphs was as follows:—"The best illustration of the fear of the people was received to-day, when a gentleman in the suburbs refused to receive a message by telephone, for fear of contagion."

. . .

TALKING of telephones brings to mind the reflection, that while the days of the four Georges, whom Thackeray loved so well, are long gone by, the "Young Pretender" is as vigorous as of yore. And if, as is frequently the case, the pretender, young, old or middle-aged, be an exploiter or inventor of a new telephone, the record of his prototype of the Georgian era is, by comparison, paled, as he goes on to tell that his instrument will talk. To modify Captain Cuttle's statement of the capacity of his watch—"It will talk: Lord; how it will talk." A specimen of this class was recently interviewed by a scribe connected with a Boston newspaper, and in sounding the praises of his very own telephone (which, by the way, was of the so-called acoustic or mechanical variety), said, and said in all seriousness, "*I can attach one of my telephones to one end of the Atlantic cable, another to the other, and talk without any trouble.*"

Certainly; but why go to the formality of attaching the telephones? The gentleman conservatively said nothing about hearing; that evidently being quite a secondary consideration. Yet when we read the above-mentioned statement, we are forcibly reminded of the boast of the biggest boy in the nursery, who alarms his mother, and fills his brothers and sisters with awe, by declaring that he can "put two chairs back to back, and then take off his shoes and jump over them."

. . .

THE way of the transgressor, it is to be feared, is being made easy. Electricity is no respector of persons, but benefits the just and the unjust alike. It has been utilized in many benevolent ways, and now as a change we have a patented invention, which to judge from its name may be an invaluable aid to the bunko man. It is one entitled a "Tester for Card *Flats*" and was issued from the Patent Office in September of this year.

Famishing Frank and Thirsty Pete have long laid snares for Hezekiah Dewtell and Samuel Buttermilk, but not until now have the latter named gentlemen been obliged to present themselves for examination as to their fitness for plucking.

This business being chiefly carried on in New York, it would seem fitting that if Mayor Hewitt's renomination result in his re-election, he should turn his attention to devising apparatus for the "protection of card flats;" whereupon the pleasing young card *sharp* who "knew your father when he was *so* high, Sir," will, in one particular at least (his occupation being a negative quantity), resemble the swarthy Moor who married and smothered Desdemona.

. . .

ONE observes that the unit and word-making fiend has once more begun his ravages, and that we are now to be regaled with "kines," "boles" and "barads." If this goes on much longer, we shall have to make a new Volapük, for the old one won't be able to grapple with it. But what can be expected after all, from a generation which not only swallows but likes "cablegram," that most hideous etymological mule.

A message received at New York from San Francisco, which travels through a multitude of river cables is a telegram; but a message by telegraph from London received at San Francisco is a cablegram; in the name of common sense why not "telegram" for all?

. . .

PERHAPS we shall have "phonogram" domesticated next; and if we are going to do that kind of thing we may as well go the entire figure.

Apropos of phonograms and phonographs, let it be noted that a literary phonograph has just been constructed by the gifted author of "Mr. Isaacs." This phonograph is a book entitled "With the Immortals;" Mr. F. Marion Crawford's idea of resuscitating the minds and souls of such immortals as Julius Cæsar, Pascal, Dr. Johnson, Heine, and others, is not so new as to entitle him to a broad claim, but it is well elaborated, and suggests a not unfavorable comparison with Walter Savage Landor's "Imaginary Conversations." Mr. Crawford has, one thinks, some trouble in catching the souls of Cæsar, Heine and Pascal, and in making them talk naturally; but his phonograph copies with considerable skill the oracular utterances which seem naturally to fall from the lips of the great lexicographer.

. .

A DOG cart has been built in London by a firm of unbelieving giaours, and fitted with an electric motor made by Immisch & Co., of London, for the Commander of the Faithful himself, Abdul Hamid Khan, Sultan of Turkey. It cost $1,000, carries four persons, and is said to closely resemble in general appearance a regular British dog cart.

If his majesty's esteemed predecessor, the late Abdul Aziz, had been asked even to ride in a dog cart, his horrified cry: "Is thy servant a dog, that he should do this thing?" can easily be imagned.

But Turkey as well as the sun "do move."

ARTICLES.

A POCKET GALVANOMETER.[1]

BY AIKITU TANAKADATE.

(Assistant to the Professor of Physics, Imperial University, Tokio, Japan.)

§I. COILLESS POCKET GALVANOMETER.

If a permanent magnet be fixed by an axis through its magnetic axis, it will be perfectly restrained from responding to external magnetic influences. But if the magnet be fixed by an axis which is only parallel to, and not coincident with its magnetic axis, it will still be in neutral equilibrium in a uniform magnetic field. In other words, a magnet so supported cannot be distinguished from non-magnetic bodies whatever be the strength of the field so long as this remains uniform; induction being neglected for the time.

If one or any number of small bar magnets be vertically attached to a suspended piece of wood, or if a horseshoe magnet be hung by a string, as in figure 1, such a system may be realized. The astatism is quite independent of the number of magnets, as each several magnet is in neutral equilibrium.

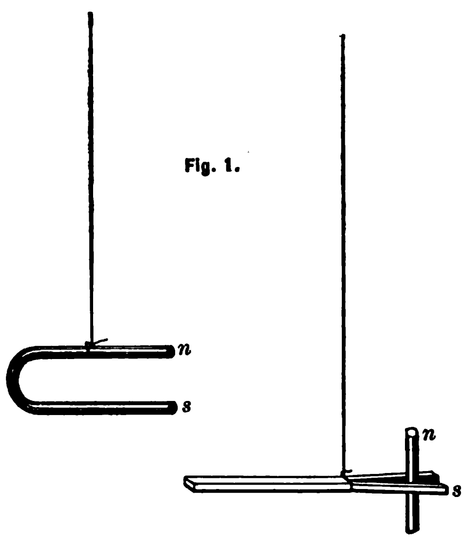

Fig. 1.

In such a state of equilibrium, if a pole of another magnet, or a wire conducting a current be brought near, the first magnet will be pulled or pushed as the case may be, so as to rotate round the fixed axis; the only necessary condition being that the forces acting on the two poles of the magnet shall be unequal, as will generally be the case in the neighborhood of a straight conductor. The circumstances of rotation will depend upon the strengths of the magnet and of the current respectively.

Any small portion of a closed electric circuit may be looked upon as the edge of a large magnetic shell. Now, if two opposite poles of a small magnet be placed close to the edge of such a shell at equal distances from the edge, the electro-magnetic force acting on the magnet will be constant, provided the line joining the two poles always passes through the edge of the shell, no matter how the other portions of the shell may lie with regard to the magnet. If four poles in rigid connection be placed about such an edge, it will be possible to find such an arrangement of the poles that the force acting on the system of the poles will be sensibly constant when the edge is within a certain portion of space between the four poles.

Thus it becomes possible to construct an instrument which will measure the strength of such a shell without breaking its continuity, and that independently of the uniform field in which the shell may be situated. That is, an instrument which will measure the current without breaking the circuit and which can be used in any position and in any uniform field. This is the idea upon which the apparatus to be described is constructed. It is indeed simply a modified form of an astatic galvanometer.

The following is one particular form of the apparatus:—Four small bar magnets are fixed symmetrically at the four corners of a thin rectangular plate of wood, which can rotate as a whole about a fixed central axis perpendicular to its plane and parallel to the magnets, as shown in figure 2. What we want to measure is the couple about this

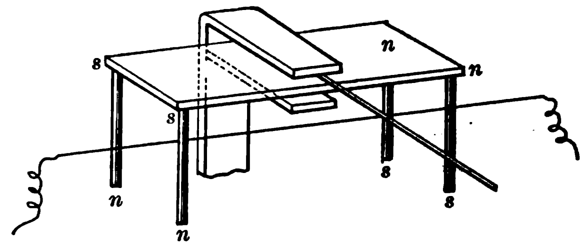

Fig. 2.

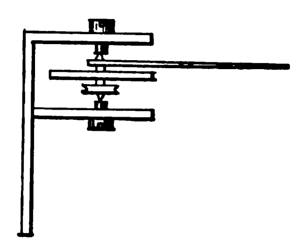

axis. We may accomplish this by means of two springs, one attached to the frame, the other to an index, and both springs initially stretch very much as in an ordinary aneroid barometer. The motion of the index is magnified by means of a multiplying lever introduced between the index and its spring, as shown in figure 4. As we cannot use steel springs, an alloy of gold and brass, which is used in making springs for *pince-nez* eyeglasses, answers here very well. Ordinary brass springs, however, are easier to make, although they are not quite so lasting.

The whole arrangement is then put in a case with a jaw-like vacant space hollowed out for receiving a conducting wire. The axis for the index projects above a graduated circular plate, and the index is fixed at right angles to the jaw, in such a way that when part of a circuit is slipped in within the jaw, the index will be moved toward that side to which the current is passing; in other words we may imagine the tip of the index to be carried by the current. The value of the indications depends upon the strengths of both the magnets and the springs, and has to be obtained by comparison with some standard galvanometer; and this calibration must be repeated occasionally as with other instruments of a similar description.

There is one inconvenience, however, in this system, namely, that the four magnets placed round the current have all their axes perpendicular to the direction of the current and consequently they are subject to the effect of induction. The induction will be positive for the two approaching magnets (that is their moments will be increased), and negative for the receding two. The total effect on the system will be nearly nil for small currents; but with large currents the magnets may be permanently affected and may even be reversed in magnetization. We can get rid of this inconvenience by fixing the four magnets to an axis which is perpendicular to each axis of the magnets, as in figure 3. It will be seen that the system is exactly the same as the previous one, if the four magnets be of equal moments or if they satisfy the condition $\Sigma M = 0$ with respect to the fixed axis. The former

1. From the Journal of the Science College, Imperial University, Japan. Vol. i.

condition we can not hope to attain in practice, but the latter can be approximated to thus:—

Make some 10 or 20 magnets of the same steel wire and leave them for some months or even for years, until the

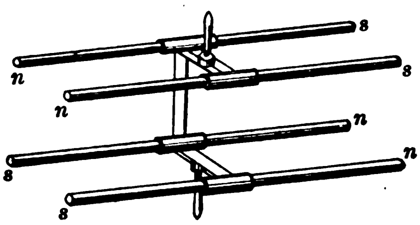

Fig. 3.

time rate of the fall of moments becomes insensible. Then measure the moment of each magnet by any of the ordinary magnetometric methods, such as the deflection of a mirror magnetometer at a constant distance from each magnet, a knowledge of the relative strengths only being essential. The magnets I used in one arrangement had the following relative moments.

(a)	(b)	(c)	(d)
313.3	311.7	312.0	313.0

This gives $(a) + (b) = (c) + (d)$ within the errors of experiment, an arrangement which was accordingly adopted. We may notice here, that if the determination of any one of them were in error of 1 in the unit figure, its uncompensated effect would be $1/\Sigma M = 1/1250$ of the whole.

In other details of construction this form of apparatus is exactly the same as the previous one, except that the jaw is side-wise instead of vertical. This gives a greater precision to the instrument as will be seen immediately, and still more facilitates the introduction of the coils of fine

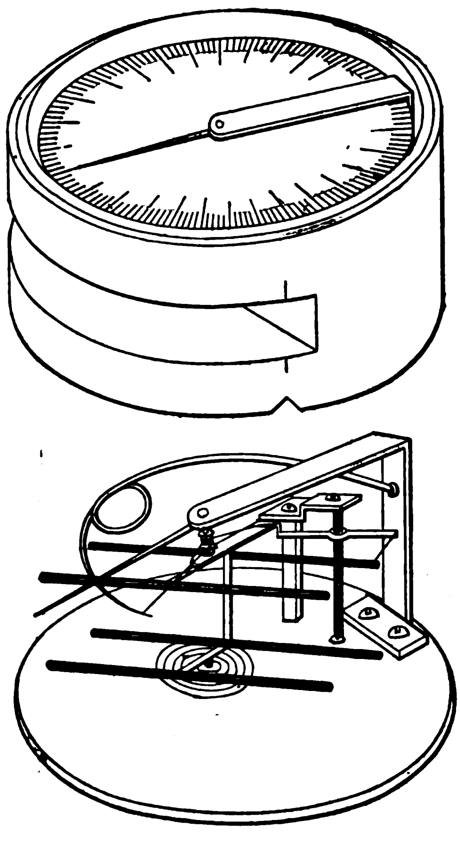

Fig. 4.

wire for measuring large differences of potential and small currents in the way to be described further on. The above cut shows one of the working instruments.

In calibrating the instrument, it is best to use a small current repeated many time instead of a single strong current, which is so difficult to keep steady. For this, 200 turns of a fine insulated wire were wound round in the form of a circular ribbon having a circumference of about 1 meter. The wires were tied together with a string so that the external appearance was like one thick insulated wire of circular section; one portion of this was put into the jaw, the remaining portions being as far removed as possible from the instrument. A current from 20 Daniell cells was passed through the ribbon; a standard tangent galvanometer and a resistance box being in the circuit. Simultaneous readings of the standard galvanometer and the pocket instrument were taken for different strengths of current, obtained by varying the resistance. From these the value of the current corresponding to 1 division of the pocket instrument was easily calculated. The following table gives the results of the comparison thus made with the working apparatus :—

Standard Galvanometer.		Pocket Galvanometer.	
Reading.	Reduced to amperes	Reading.	Value of 1 division in amperes.
12.0	.0350	12.4	.565
19.7	.0575	20.6	.558
28.9	.0844	30.5	.554
35.5	.1037	37.4	.555
		Mean	.558

As the instrument was graduated to 100 divisons we could measure with this up to 56 amperes, and, as will be seen later, by placing the wire below the instrument up to 168 ($= 3 \times 56$) amperes. In making the comparison, we must place the standard galvanometer at a considerable distance from the ribbon, which becomes a strong magnetic shell when the current is passing. In fact it is best to put the two instruments on different tables, and make two series of observations, one with the current direct and the other with it reversed. For measuring a moderate current, such as 1 or 2 amperes, we can advantageously repeat the circuit three or four times by simply coiling the conductor so as to make a temporary ribbon like that just described.

By altering the points of support of the springs (as in the time rating of a watch) we may, if it is required, adjust the instrument so as to make one division correspond to some simple fraction of an ampere, say .5 or .2

FIELD OF FORCE AND ARRANGEMENT OF MAGNETS.

In studying the field of force due to four magnets arranged as in figure 4, and a single straight conductor parallel to their axes, we have only to consider the action of a single straight conductor upon one set of four poles which lie in a plane perpendicular to the conductor, since the other set of poles is an exact counterpart of the one considered. As proved in Maxwell, the electro-magnetic force at an external point of a straight cylindrical conductor of infinite length depends only upon its distance from the centre of the section, for any concentric distribution of current; and since the action between a magnet and a current is mutual, if a compound cylindrical magnet consists of concentric layers of uniform intensities, its action upon an externally placed current running parallel to the axis of the magnet, must be reducible to the action of a single equivalent pole at its centre, whatever be the law of distribution of magnetism from layer to layer. As we make our magnets of cylindrical wire, and as most conductors are cylindrical, we may safely reduce the action to the centres of the sections of the magnets and the conductor, neglecting the pole-shifting effect due to the induction of magnets on each other.

Let $2a$ be the distance between like poles, and $2b$ that between unlike ones; and put r for $\sqrt{a^2 + b^2}$.

Let x, y be the co-ordinates of any point referred to the centre of the rectangle $[2a, 2b]$, measured parallel to a and b respectively.

Let ξ η be the co-ordinates of any one of the poles, referred to *any position of the current as origin*, so that if x, y be the co-ordinates of the current,

$$\xi + x = a \text{ and } \eta + y = b$$

Then $\rho = \sqrt{\xi^2 + \eta^2}$ is the distance of any pole from the current.

The potential energy of unit current and four unit poles is

$$V = 2\,\Sigma \tan^{-1}\frac{\eta}{\xi} + const. = 2\,\Sigma\,\theta + const. \quad (1)$$

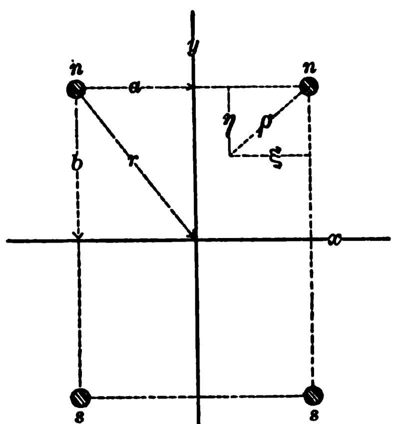

Fig. 5.

Σ meaning summation for the four distinct poles and θ being the angle between any of the polar distances and the axis of ξ. V then reduces to the algebraic sum of the two angles subtended by the two parallel lines of length $2b$ placed $2a$ apart. This is the same as the potential energy of unit pole and two parallel magnetic strips of infinite length placed $2a$ apart, the breadth of each being $2b$. The solid angles ω_1 and ω_2 of the usual notation become two spherical wedges. The two magnetic strips may be replaced by two equal pairs of parallel currents, placed along the edges of the strips, as will be evident *à priori*, since the action of a unit current upon four unit poles must be the same as that of four currents upon a unit pole so far as the dynamical aspect is concerned. This latter was the combination I used in making an experimental verification of the result.

From (1) the equation

$$\Sigma\,\theta = const.$$

gives the equi-potential surfaces, and

$$\Sigma \log \rho = const.$$

gives the lines of force. Figure 6 shows a special case of such a field.

To determine the best arrangement of the magnets so as to minimize the error due to the eccentric position of the current (which is the same thing as that due to the deflected position of the magnets) we may proceed to find the electro-magnetic forces acting upon the system of magnets, when the current is placed in any position, x, y. Putting F for this force and expanding it in terms of eccentric displacement δx, δy, we have,

$$F = F_0 + \frac{\delta F}{\delta x}\delta x + \frac{\delta F}{\delta y}\delta y$$

$$+ \frac{1}{|\underline{2}}\left\{\frac{\delta^2 F}{\delta x^2}(\delta x)^2 + 2\frac{\delta^2 F}{\delta x\,\delta y}(\delta x)(\delta y) + \frac{\delta^2 F}{\delta y^2}(\delta y)^2\right\}$$

$$+ \frac{1}{|\underline{3}}\left\{\frac{\delta^3 F}{\delta x^3}(\delta x)^3 + 3\frac{\delta^3 F}{\delta x^2\,\delta y}(\delta x)^2(\delta y) + 3\frac{\delta^3 F}{\delta x\,\delta y^2}(\delta x)(\delta y)^2 + \frac{\delta^3 F}{\delta y^3}(\delta y)^3\right\} + \cdots\cdots$$

where F_0 is the force at the origin. On account of the symmetry of configuration, the terms containing odd powers of either δx or δy vanish when taken for all the four magnets. The equation then reduces to

$$F = F_0 + \frac{1}{2}\left\{\frac{\delta^2 F}{\delta x^2}(\delta x)^2 + \frac{\delta^2 F}{\delta y^2}(\delta y)^2 + \frac{\delta^4 F}{\delta x^4}(\delta x)^4 + \cdots\cdots\right\} \quad (2)$$

where $$-F = \frac{\delta V}{\delta x} = \frac{\delta}{\delta x}2\,\Sigma\,\tan^{-1}\frac{r}{\xi}$$

but since $$\left.\begin{array}{l} x = a - \xi \\ y = b - r \end{array}\right\}$$

$$\frac{\delta^n}{\delta x^n} = (-1)^n\frac{\delta^n}{\delta \xi^n}$$

$$\frac{\delta^n}{\delta y^n} = (-1)^n\frac{\delta^n}{\delta \eta^n}$$

$$F = \frac{\delta}{\delta \xi}\Sigma\,\tan^{-1}\frac{\eta}{\xi} = \Sigma\,\frac{-\eta}{\xi^2 + \eta^2}$$

also $$\frac{\delta^n}{\delta \xi^n}\left(\frac{\eta}{\xi^2 + \eta^2}\right) = \frac{(-1)^n\,|\underline{n}\,\sin(n+1)\,\theta}{(\xi^2 + \eta^2)^{\frac{n+1}{2}}}$$

$$\frac{\delta^n}{\delta \eta^n}\left(\frac{\eta}{\xi^2 + \eta^2}\right) = -\frac{(-1)^n\,|\underline{n}\,\sin(n+1)\,\theta}{(\xi^2 + \eta^2)^{\frac{n+1}{2}}}$$

$$\tan\theta = \frac{\xi}{\eta} \qquad \text{as before}$$

Thus, taking only the increment of force, we get from equation (2)

$$\Delta^2 F = -\,\Sigma\left(\frac{\sin 3\,\theta}{\rho^3}\delta x^2 - \frac{\sin 3\,\theta}{\rho^3}\delta y^2 + \cdots\cdots\right)$$

but when δx and δy are each small ρ becomes very nearly r, and θ may be regarded as measured from the centre of the rectangle $[2a, 2b]$. We may then dispense with the sign Σ in discussing the configuration. Thus if

$$3\,\theta = \pi \text{ or } n\pi$$

or $$\theta = \frac{\pi}{3} \text{ or } \frac{n\pi}{3}$$

the coefficients of $(\delta x)^2$ and $(\delta y)^2$ vanish simultaneously. In other words if the magnets are arranged occupying any four opposite corners of a regular hexagon, that is if a/b be nearly $4/7$*, the error due to a small displacement will be eliminated up to the third order of the displacement inclusive.

The simultaneous disappearance of the coefficients of $(\delta x)^2$ and $(\delta y)^2$ might indeed have been anticipated from the general equation $\Delta^2 V = 0$ since V is here function of only x and y we have

$$\frac{\delta}{\delta x}\Delta^2 V = \frac{\delta^2}{\delta x^2}\frac{\delta V}{\delta x} + \frac{\delta^2}{\delta y^2}\frac{\delta V}{\delta x} = 0$$

now $\delta V / \delta x$ is F. Hence when either of $\delta^2 F / \delta x^2$ or $\delta^2 F / \delta y^2$ vanishes the other must do so too.

The uniformity of the field arrived at by this arrangement is shown by the following diagram of equi-potential lines and lines of force. Curves representing the intensities of forces along the co-ordinate axes and the diagonal are also given.

FIELD OF FORCE.

$$a^2 : b^2 : r^2 = 1 : 3 : 4.$$

*Practically it will be found better to make a/b somewhat larger than $4/7$, so to obtain a greater range of uniformity in the field.

The general expression for the force is

$$-F = \frac{\delta}{\delta x}\, 2 \, \Sigma \tan^{-1} \frac{\xi}{\eta}$$

$$= 2 \left\{ \frac{b-y}{(b-y)^2 + (a-x)^2} + \frac{b-y}{(b-y)^2 + (a+x)^2} + \frac{b+y}{(b+y)^2 + (a-x)^2} + \frac{b+y}{(b+y)^2 + (a+x)^2} \right\}$$

If, now, we make

$$\left.\begin{array}{l} x = 0 \\ y = 0 \\ \rho = x\dfrac{a}{r} = y\dfrac{b}{r} \end{array}\right\} \text{successively}$$

we obtain the expressions

$$\left.\begin{array}{lll} F = \dfrac{8\,b\,(r^2 + x^2)}{(r^2 + x^2)^2 - 4\,a^2\,x^2} & \cdots\cdots(\alpha) & \text{along } x\text{-axis} \\ F = \dfrac{8\,b\,(r^2 - y^2)}{(r^2 - y^2)^2 + 4\,a^2\,y^2} & \cdots\cdots(\beta) & \text{“ } y\text{-axis} \\ F = \dfrac{4\,b\,r^2}{r^4 + r^2\,\rho^2 + \rho^4} + \dfrac{4\,b}{r^2 - \rho^2} & (\gamma) & \text{“ diagonal} \end{array}\right\} \text{respectively.}$$

The maxima and minima of these are given by

$x = 0$

$x = \pm \sqrt{r\,(-r \pm 2\,a)}$ .... (α')

$y = 0$

$y = \pm \sqrt{r\,(r \pm 2\,a)}$ .... (β')

$\rho = 0$

$\rho = r$ (others being imaginary) ... . (γ')

from which we see that the pairs of maxima are superposed at the origin if $r = 2a$, which is equivalent to $\theta = \frac{\pi}{3}$. The minima along the y-axis at $y = \pm \sqrt{r\,(r + 2\,a)}$ are always real for any ratio of a/r. In the present case, the values become $\pm 2\sqrt{\frac{2}{3}}\,b$. Substituting this value of y in (β) we get the value of F there $= -\frac{1}{3} F_0$. It will be seen that at each of these points, the lines of force begin to change their curvature, and the field is sensibly constant. By constructing the instrument so that the base lies just above one of these points, we adapt it for the measurement of very strong currents, such as 100 amperes or greater. To facilitate such a measurement a **V**-groove is cut out along the base in the proper position, and into this the circuit bearing the current is received. To reduce the value thus obtained to what it would have been, had it been placed in the jaw, we have only to multiply the reading by -3.

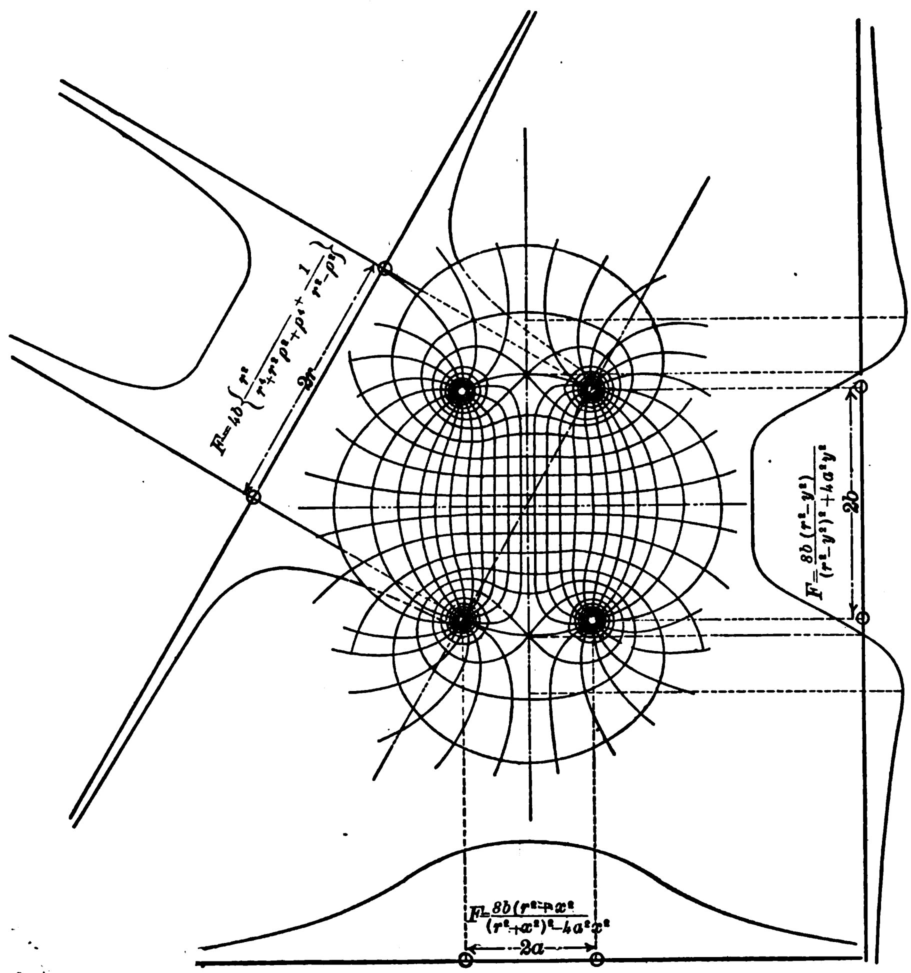

Fig. 6.

The following table giving the proportional decrement of force for given displacements of the magnets, will show to what amount of displacement we may, without sensible error, assume the uniformity of the galvanometer constant as obtained by calibration for small displacements. Computing $(F - F_0) / F_0$ we have

Along x-axis.		Along y-axis.		Along diagonal.	
$\delta x/a$	$\delta F/F_0$	$\delta y/b$	$\delta F/F_0$	$\delta \rho/r$	$\delta F/F_0$
1/4	1/4161	1/4	1/435	1/4	1/445
1/3	1/1333	1/3	1/133	1/3	1/132
1/2	1/273	1/2	1/24	1/2	1/21
1	1/21				

As long as the deflection is within $\frac{1}{2}a$, the error will be less than 1/2 per cent. and when it is to the extreme limit of a, the error will be about five per cent. It is interesting to notice that δF is very nearly proportional to the fourth powers of δx, δy, $\delta \rho$, even when these are $\frac{1}{2}a$, $\frac{1}{2}b$, $\frac{1}{2}r$. The above table enables us to adjust the range of the index and the jaw of the instrument so as to keep the magnitude of errors within any assigned limit. In the actual instrument constructed the width of the jaw was $\frac{1}{2}b$, and the deflection was limited to $\frac{1}{2}a$, so that the error fell within $\frac{1}{273}$ for any reading, even if we suppose the eccentricity in the direction of y to be as much as $\frac{1}{4}b$.

To verify the results thus far obtained the following experiment was made in the Physics Laboratory of the Science College of the Imperial University:—Six blocks of wood, each 21 cm. high and 13 cm. wide were arranged in a row upon a long laboratory table extending through a space of 3.7 meters along the magnetic meridian. These blocks served simply as guides for the stretching of two rectangular coils of insulated wire, whose distance apart bore to the height of either the ratio required (tangent 30°). Each coil consisted of six turns. Thus were obtained two parallel magnetic strips of practically infinite length.

One of Thomson's graded galvanometers with its field magnet taken away, was placed in the space between the two central blocks, its V-groove lying along the magnetic east and west line. The height of the galvanometer was so adjusted that the centre of the four small magnets, belonging to the fan-shaped compass, was always in the plane half way between the upper and the lower lines.

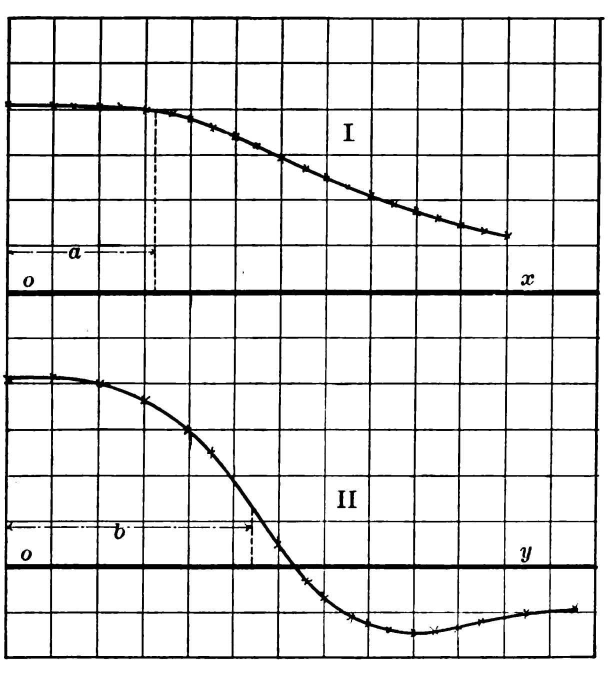

Fig. 7.

A current was run round the wire and was left for about 20 minutes till its flow became steady, and then the compass was slid along the V-groove, and its position and deflection simultaneously observed at several positions. From these observations the curve I, in figure 7, was obtained. By a slight modification of the arrangement, providing a vertical V-groove, the compass was made to move along a vertical line; and from a similar series of observations the curve II was obtained. These should be compared with the curves of figure 6.

It will be seen that the system of magnets thus arranged is equivalent to Helmholtz's galvanometer of two circular coils, if we imagine the two coils to be deformed into two long rectangles of infinite length, that is, reduced to four parallel currents. For if we adjust these currents to proper positions, and replace each of them by a magnet and the central magnet by a straight current, we have the system just discussed.

(To be continued.)

SOME OBJECTIONS TO THE OVERHEAD CONDUCTOR FOR ELECTRIC RAILWAYS.[1]

BY M. B. LEONARD.

Of all the valuable papers read before the Institute, probably none has excited greater interest than Mr. Sprague's admirable contribution on "Electric Railways the Solution of the Municipal Rapid Transit Problem," in which the advantages of electricity in practical operation have been so well set forth as to convince the most skeptical of its superiority over all other methods of traction for this class of traffic. Although the paper was written with special reference to the adaptability of electricity in solving the problem of rapid transit in the great City of New York, the benefits resulting from this system of propulsion may be obtained equally as well elsewhere, and prove to be as permanent as we have found them in our historic City of Richmond.

To electrical engineers this comparatively new application of the electric current is one of the most important questions that have come before them, and should be carefully studied in all its details, so that the defects and objections may be pointed out and provided against, and the most perfect methods devolved as speedily and fully as possible. But in working this question out it must be remembered that "the most haste, the less speed," and that before undertaking to surpass the locomotive it is wiser to prove its superiority over the horse or mule. Having accomplished this successfully, then it is time to endeavor to rival steam. In attempting what has been aptly described as "feats of sensational engineering," it should always be borne in mind that failure inevitably deals a severe blow to the whole cause of electric traction, the general public not always inclined to discriminating in such cases, as will be remembered from the accident which occurred to a number of capitalists and prominent people some years ago, who were engaged in testing the traction system of a well-known electrician.

A second point of the utmost importance is the necessity for first-class workmanship. Anything worth doing at all is worth doing well, and particularly is this the case with the utilization of a new force. This is so self-evident as to require no further comment.

While it has been successfully demonstrated in the City of Richmond that electric traction is really the solution of the rapid transit problem, and we have felt, in the increased value of real estate and the growth of our city in population and reputation, the substantial benefits resulting therefrom, I have considered from my daily observation of this electric road that the overhead wire system cannot be made a perfect or ideal method of operation under all circumstances, because of the defects inherent in such a method. But that it will serve as a pioneer in the new

1. Read before the American Institute of Electrical Engineers, New York October 9, 1888; in discussion of Mr. F. J. Sprague's paper on The Solution of Municipal Rapid Transit, read before the Institute June 19.

field and will be supplanted in time by a more perfect system, I have not the least doubt; and in the following remarks I will endeavor to show some of the objections that have come to my notice, although there may be others that have escaped my attention, owing to the extreme reticence of all parties connected with the enterprise, doubtless from business reasons.

Of the three most commonly used, the overhead system appears to be the favorite. The latest report of electric street railways in operation in America shows that out of a total of 43, not less than 36 are using the overhead system and that at least 30 now under construction have arranged to do so. Doubtless the smaller cost as compared with the other two was an important factor in deciding so largely in favor of the overhead conductor.

As used in Richmond, the details of operation have been shown so fully and clearly in Mr. Sprague's paper that it is unnecessary to repeat them here, beyond stating that the rail and earth system is adopted in connection with the overhead wire.

During the seven months of active operation of the Richmond Union Passenger Railway, many thousands have been successfully transported every day and at a very much lower cost than could possibly have been done by horse-power, owing to the excessive grades encountered; but the defects of the overhead system are now becoming more apparent as the plant suffers its material depreciation, and we are now in a better position to judge of its value as a permanent institution than we could possibly have done heretofore.

It is an undisputed fact that the encumbering of the streets with the poles required for the overhead system is one of the most serious objections to its use, although they are hid to a large extent in many places by the shade trees and foliage, yet on the main streets of our cities where this system is most likely to be used they are not only a grievous eyesore but also increase the liability to accident from runaway horses and other causes. Their appearance would not perhaps be so offensive were it possible for them to maintain an erect position, but on account of the weight of the trolley wires, and the pressure of the trolley, the tops of the poles are constantly pulled together notwithstanding they may have at first been raked in the other direction, and thus the unsightly effect is augmented.

Those of us who are acquainted with telegraph line construction, can appreciate the great leverage exerted by a heavy strain on the top of a pole 25 or 30 feet high, unsupported by guys or otherwise, and will readily understand that it is only a question of time before the poles must be reset or replaced with heavier ones. This has been especially the case on the curves where the strains have been greatest, in some instances approximating a pull of 650 lbs., nor does the network of wires, span, trolley, guard and curve, inspire the public with any feeling of toleration for the disfiguring of its streets, but must hasten the time when the clamor for underground wires will compel their removal.

But to my mind the most serious objection is the employment of the bare trolley wire carrying a current of 500 volts and about 90 amperes, which I consider not only dangerous to life on account of the frequent breakage of the wire, which on one occasion last spring in falling struck and killed a horse, but also in damage to property by fire. It is claimed that the use of guard wires will always prevent the possibilities of such an occurrence, but the guard wires did not obviate the burning and melting of the telephone wires when on one occasion the breaking of an exchange telephone pole threw them across the trolley wire, and it was necessary to shut down the railway to prevent the entire destruction of the exchange and possibly the firing of the subscribers' instruments and houses.

That the trolley wire is liable to breakage at any time has been shown twice during the past week to the interruption of travel and dissatisfaction of the public. While not so very long ago the wires over one of the curves were pulled down on top of the car by the trolley catching in it, and travel entirely suspended on that part of the line for one or two days.

A very serious defect in the use of the bare trolley is the difficulty of securing proper insulation. Thus far porcelain knobs seem to have been found best adapted for this purpose; and the leakage resulting, especially in damp or rainy weather, must be considerable on the whole length of the line, and must cause a large waste of current. This is probably the reason why it has been impracticable to run over about 30 cars at one time out of the 40 with which the road is equipped, and would seem to indicate a very large loss of energy.

In view of the fact that porcelain insulators have been long ago condemned for telegraph purposes where a comparatively small current is used, it seems strange that they should have been adopted as the best means for securing insulation in circuits of such high potential as are employed on the Richmond road.

The trolley itself seems to be a clear source of trouble and difficulty to manage properly. As has been shown, it consists of a grooved wheel at the end of a counterbalanced pole held by a spring against and making contact with the under side of the working conductor. In rounding curves it must be carefully watched by the car conductor to prevent it leaving the trolley wire and thus stopping the car, and at night extinguishing the lamps, which has proved exceedingly disagreeable to the passengers, while on busy days it has seemed necessary to put a third man on at each car at additional expense for the sole purpose of attending to the trolley. Sometimes the trolley pole has broken or the springs holding it against the wire given way, stopping further progress of the car or requiring a man to stand on the car roof holding the trolley pole against the wire until the repair sheds were reached.

One of the most unsatisfactory features about the arrangement of the Richmond road is the ground circuit, not only because of the difficulty of getting a good ground, which has in this case only been accomplished by connecting the track with the whole gas or water works system of the city to the detriment of our exchange telephone system (so well described by the telephone superintendent, Mr. McCluer in his paper before the recent telephone convention), but the fact that it is necessary to have a clean track to work on; otherwise vivid flashes of electricity will appear, to the terror of the horses in the vicinity and damage to the motor, or should it happen that there is a sufficient quantity of dirt on the rail it will cause a higher resistance than the potential of the current can overcome and, of course, stop the car. Should the motor man get off to push it over the dirt and fail, as sometimes happen, to switch off the current from the motor, the full current on the line will pass through it just as soon as a good contact is made and the result is a burnt armature and a disabled car. This seems to have been particularly the case during the recent stormy weather, when I am imformed that the number of available cars for traffic on the road was reduced to about ten. Possibly the saturation of the motor by the rain and the effect of lightning on the trolley wire had also something to do with the case. Owing to the reticence of the employés above referred to, it has been difficult to ascertain just what damage has been caused by lightning striking the trolley wires and injuring the motors, but that there has been serious trouble from this source, I have no doubt. The very best forms of lightning arrestors have not proved sufficient to prevent injury to electric light dynamos where insulated wires are used on the outdoor circuits, while the bare wire used for the working conductors on overhead electric traction systems must always render them more susceptible to trouble from this direction.

After setting forth the difficulties which have been shown in the practical operation of the most extensive system of electric traction in the world, it gives me pleasure to direct

attention to the remarkable behavior of the Sprague motors under all the conditions to which they have been subjected for the past seven months, which has been indeed remarkable. No load has been too heavy and no grade too steep for them to ascend. Perhaps the severest test they ever received was on the night of July 4th, in bringing the crowds from the new Reservoir Park, when the ordinary open cars carried over 100 passengers and the closed cars over 75 each, so many in fact that the axles of one or two of the cars broke down under the load; all of which must be exceedingly satisfactory to the inventor, and places the Sprague motor at the very head of the many excellent types or forms that have been devised at home and abroad.

The objections referred to above apply equally as well to all forms of overhead systems, except where a second wire is used for a return instead of the track and earth, and also where the trolley pole is discarded for the movable trolley. But the increased number of aerial wires required as well as the heavier fixtures needed to sustain them render these systems just as objectionable.

We are very anxious to see the effect of ice, sleet and snow upon the operation of our road, as it has not yet passed through a winter in complete running order. A heavy sleet storm has often prostrated our telegraph lines, and I see no reason why the overhead electric railway wires would be exempted from similar trouble, nor why the covering of the rails by ice and snow will not render it difficult to make a sufficient contact to operate the line successfully, not to speak of the loss of current by leakage or escape from the trolley wire; but I have no doubt that the ingenuity of those who have overcome all the problems encountered in opening up with such success The Richmond Union Passenger Railway, will be sufficient to insure its continued operation in spite of wind and weather, and to no one more than myself, will this be gratifying, since it was through my efforts that attention was first directed some three or more years ago, to the splendid opportunities for electric traction that Richmond presented, although I am free to confess that my inclinations were towards the application of the storage battery, which obviates all the troubles and defects developed by the overhead systems, and against which no more serious objections seem to be brought than the extra weight caused by the batteries and the greater first cost as compared with the aerial systems, all of which, it appears to me, are more than counterbalanced by the difficulties and annoyance in the systems just described.

The very satisfactory results obtained in the operation of the new electric storage cars on the Fourth avenue railroad in this city, as well as by Mr. Wharton, of Philadelphia, Mons. Huber in Brussels, and elsewhere, prove, as I have believed, the storage battery to be the only ideally perfect system of electric traction for municipal purposes.

NOTE ON GEARING FOR ELECTRIC RAILWAY MOTORS.[1]

BY ALMON ROBINSON.

PROBABLY no one will be disposed to deny that in devising a connection for the motor and the car wheels, what Mr. Sprague attempted to do, has been done extremely well. Has he attempted all that is desirable?

Mr. Sprague's investigations have shown that, in street car work, a very large percentage of the whole power used is expended in starting the cars. Now it seems to me, that a motor whose speed has a fixed ratio to that of the car wheels must work uneconomically when the car is moving slowly, for no amount of skill spent in varying the magnetic circuit can prevent an armature from wasting a current sent through it when it is practically standing still. It would seem, therefore, that wide variations of speed and load would make it necessary at times to weaken the field to an uprofitable extent.

1. Read before the American Institute of Electrical Engineers, New York, October 9, 1888.

Perhaps, however, Mr. Sprague may be able to show that a properly designed motor will work with a high efficiency in doing anything which he puts upon it in railroading.

But, even in that case, there would still remain the extra cost and extra weight of a motor large enough to lift its heaviest load by a dead pull.

To do the hardest part of his work, Mr. Sprague is really using a thing in which he disbelieves—a slow moving motor.

In the storage car problem this matter of weight, bulk and cost, becomes the most important element. Here, the present practice is simply: The hauling about of ten men to do by main strength what one man could do by a lever.

The desirability of a variable leverage for the motor has not escaped the attention of experimenters. In Mr. Henry's Kansas City work, an arrangement of toothed gearing and clutches was tried. I have never learned whether this particular feature proved a help or a hindrance; nor whether it is in use on the Henry road said to be running at San Diego, Cal. A prominent inventor has expended a good deal of ingenuity on the details of a plan making use of reciprocating friction pawls. Mr. Reckenzaun tried and abandoned a leather covered chain, clamped between two cones in such a way that the diameter of the circle of contact could be varied.

Mr. Van Depoele has suggested, and I presume, tried a connection having two different speed ratios, in which friction gears were used. For this particular purpose (furnishing a variable speed ratio) I am obliged to confess myself a believer in the possibilities of frictional gearing.

For electric railroad work, it is certainly under a cloud at present. Those who have used it most, like it least. The eminent engineer, who, about a year ago, read a paper before the Institute on "Methods of Gearing," seemed to consider that it had been sent to its last resting place by the experts who tested some of Professor Fleeming Jenkin's devices.

No one seems to notice that every day, and on every railroad this method of transmission gets the roughest possible testing; that every locomotive pulls its train by frictional adhesion; that a rail and driving wheel are neither more nor less than a frictional rack and pinion. When we try to copy the work of the locomotive under other conditions our troubles begin. But no man who has ever seen a freight engine climb a grade has any right to speak with disrespect of frictional gearing.

The real root of all the difficulties with frictional transmission seems to be that the pressure producing adhesion does not vary with the dimensions of the gearing; so that when we reduce the size and increase the speed of the gearing the friction at the journal bearings soon becomes enormous. For light work this is partly obviated by using, instead of metal, some more adhesive material, such as paper, rawhide, etc. But none of these surfaces will stand a pull at all comparable with that on the surface of a locomotive driving wheel.

The most promising methods would appear to be those in which the pressure is prevented from acting across the bearings. This idea is carried out to some extent in the well-known V-grooved gearing; but the unavoidable sliding and grinding of the surfaces makes it impossible to obtain a high duty from it. The idea is more fully carried out in the devices of Sillers, Jenkin, and others. I do not know that anything has been suggested—I certainly cannot suggest anything—which does not leave, for the purpose under consideration, much to be determined by trial. Knowing well the effect which actual trial is apt to have upon untried devices, I cannot blame an engineer who prefers to let well enough alone, if a fixed speed ratio is all that he cares for. But I cannot help thinking that a usable connection, which left the speed of the motor independent of that of the car, would be a valuable acquisition; and that a probability of obtaining it would amply justify further experiments with methods of gearing.

ELECTROLYSIS OF TIN SALTS.[1]

BY ALEXANDER WATT.

(*Continued from page* 481.)

HAVING obtained these results, the solution was next strengthened by the addition of more tin salt, about five grains to the ounce, without increasing the proportion of hydrochloric acid. Figure 4 represents the crystals obtained from the solution thus modified, the curved or semi-circular cathode again being used with the current as before from one Daniell cell. Subsequently the solution was still further strengthened by adding an increased proportion of tin salt, with also a slight addition of hydrochloric acid. The results obtained from this modification are shown in figures 5 and 6, and it will be noticed what a marked difference there is between the latter examples and either of those preceding them. Indeed, from my experiments it became evident that a very slight modification in the strength of the electrolyte, or of the form of the cathode, was sufficient to cause an immediate change in the character of the crystallization, without any altera-

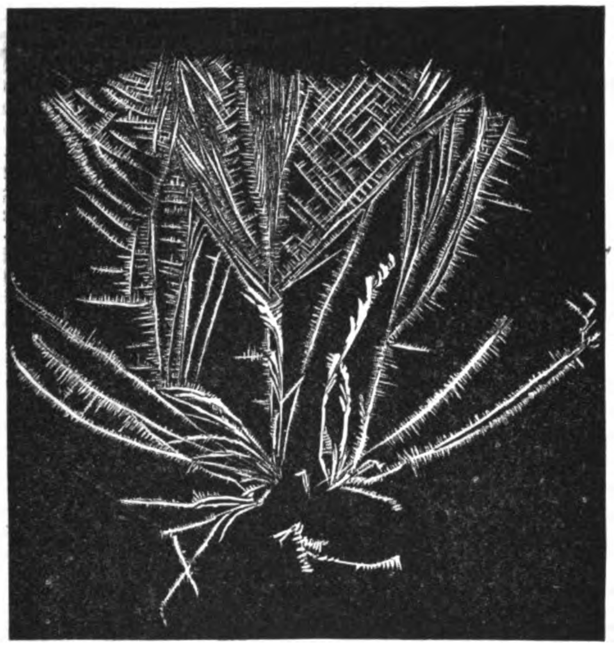

FIG. 4.

tion being made in the strength of the current. When, however, the current was increased by the addition of a second cell, this appeared to have less influence on the form of the crystals than was evidenced by increasing the metallic strength of the solution.

An attempt was next made to obtain a reguline deposit of tin from a solution of the protochloride by trying the liquid at various degrees of dilution, but it was found to be practically impossible to prevent the metal from depositing in a spongy condition unless the cathode was kept constantly in motion while in the bath. In this way, in a very weak solution, the metal could be induced to assume the reguline form, but for any practical purpose of electro-deposition a bath prepared from the protochloride of tin appears to be totally unsuited.

2. *Bichloride of tin.*—This salt was obtained by dissolving granulated tin in nitro-hydrochloric acid, and the concentrated solution thus obtained was afterwards added to water, in varying proportions, with the object of obtaining, if possible, a reguline deposit of the metal. The first bath was composed of two fluid drachms of the concentrated solution of the bichloride of three ounces of water, and the current from a single Daniell cell was employed. On immersing a brass plate in this solution, and a very small anode surface, a white film of tin was promptly obtained, and continued to retain this appearance for some minutes, but in about a quarter of an hour the film assumed a darkish color, and the deposit became pulverulent. The solution was next diluted with three more ounces of water and a fresh plate immersed, while the anode surface was also reduced. The deposit, as before, was very prompt, and of a fine white color, which it sustained for about 15 minutes, when the film gradually acquired a gray tone, due, as in the former case, to the deposited metal assuming the powdery form, though not in so marked a degree as in the first case. The bath was next again diluted by adding two more ounces of water—making eight ounces in all—and a freshly prepared brass plate put into the solution, the anode surface being still further reduced until the immersed surface was about one-eighth of that of the cathode. The deposit, though slower than in the former cases, was sufficiently rapid for a good coating, while the film was exceedingly white and perfectly reguline, which conditions were maintained for a much

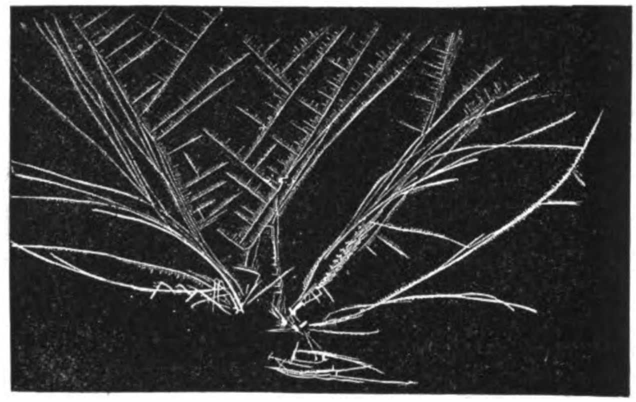

FIG. 5.

longer period than before. Eventually, however, the deposit at the lower part of the cathode assumed a gray color, and a spongy mass of the reduced metal appeared at each corner of the plate. A gelatinous mass (doubtless stannic acid) also formed in the solution, and floated on its surface in large clots. Further dilutions of the solution were subsequently tried, but it soon became evident that unless the cathode were kept in constant motion, no considerable thickness of tin, in a reguline condition, could be obtained from this solution. It was also found to be difficult to obtain crystals of the metal from solutions of the bichloride. A strip of zinc was immersed in the bichloride solution for some hours, at the end of which period it was found that this metal had deposited the tin in the form of stannic acid, which, being filled with bubbles of gas, floated on the surface of the liquid to the depth of about one inch.

3. *Tartrate of potassa and tin.*—A bath was prepared by digesting recently precipitated stannous oxide in a boiling solution of cream of tartar, for which purpose two ounces of the tartar were dissolved in 16 ounces of boiling water; an excess of

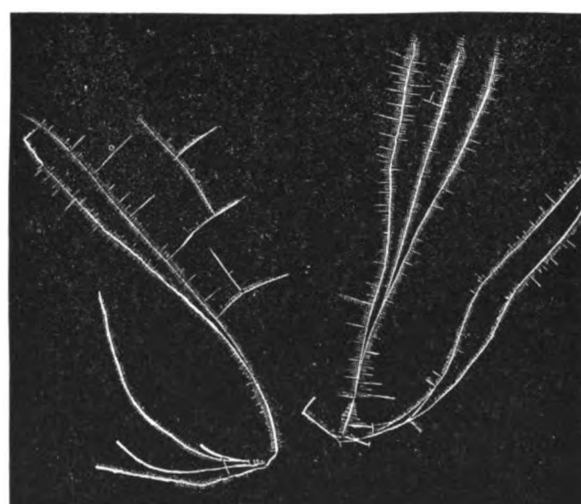

FIG. 6.

the tin oxide was then added, and the whole well stirred and kept hot for about an hour, after which the vessel was set aside to cool, when the clear liquor was decanted for use. With the current from a single Daniell, a white and bright film of tin gradually formed upon a brass cathode, but this assumed a pearly appearance after a few moments. The anode surface was about equal to that of the cathode, and there was no evolution of hydrogen. At the end of about two hours the plate had received a fairly good coating of metal, which was uniformly homogeneous and of good white color. It was noticed that the anode kept perfectly clean in this solution.

.... FOR long distances the transmission of energy is at present out of the question.—*W. H. Preece.*

1. From the *Telegraphic Journal and Electrical Review* (London).

LIGHTNING.[1]

BY S. A. VARLEY.

(Continued from page 495.)

In an earlier part of this paper I made reference to certain experiments carried through by me to ascertain the law which induction followed. The method I adopted, and the results obtained with flat plates, and also insulated circular conductors, were described in detail in a paper read before the Society of Arts in March, 1859, and published in their transactions. In the course of the description I state: "When a galvanic battery is connected with the inner and outer coatings of a Leyden arrangement, induction will take place through the dielectric, and if the surfaces of the two coatings are equal, then the force will be equally divided over them, that is to say, if the battery force be 100, the tension of the charge on the one coating will be 50, and that on the other will be 50 also = 100. Let the surface of the outer coating be infinite in extent, then the tension of the charge on the inner coating will approach infinitely near to 100, and the tension on the outer coating will be almost nil. An example of this we have when the earth represents one of the coatings of a Leyden arrangement, and this is the case in the prime conductor of a frictional machine, and also in the suspended wire of the telegraphic circuit. In these two examples the prime conductor of the machine and the wire of the telegraphic circuit represent the one coating, the air the dielectric, and the earth the other coating."

Assume a Leyden arrangement consisting of two metal plates, the surface of each of which say = 100, and the space separating them = 1.

If we charge one of these plates, which we will call No. 1, with negative electricity to, say a potential = 100, this negative charge will be balanced by a positive one on No. 2 plate having a + potential = 100.

Now reduce the surface of No. 2 plate to 10, and charge No. 1 plate as before with negative electricity to a potential = 100, this negative charge will be balanced by an equal amount of positive electricity on No. 2 plate; but as the surface of No. 2 plate is only $\frac{1}{10}$th that of No. 1, the positive electricity accumulated on No. 2 plate will be 10 times as dense as that of the negative charge, and therefore it will have a potential = 1,000, or to state it differently, it will have 10 times the force to break down the dielectric, and so bring about discharge.

If No. 2 plate were further reduced to a surface = 1, then the positive potential would be 100 times that of the negative charge accumulated on No. 1 plate, and if this negative potential, as assumed in the former examples, = 100, then the positive potential would = 10,000.

Here we have a simple explanation, which I think has been overlooked, of how it is that a needle point will discharge a charged Leyden jar through a very considerable space of air. If we could conceive a Leyden arrangement in which the metal plate of smaller surface was a mathematical point, it would be impossible to charge it, as the potential of a mathematical point would be infinitely great in all cases.

Now let us perform the experiment in a slightly different manner. Assume a second Leyden arrangement in which the surface of No. 1 plate = 1,000, the surface of No. 2 plate = 100, and the space separating the plates = 10. Assume that No. 1 plate has been negatively charged to a potential = 100.

The thickness of dielectric which will now have to be broken down for discharge to occur will be 10 times that of the first example, where the space separating the positive and negative plates = 1, and the surfaces of both plates were equal to one another; but as in this case the negatively charged surface has been increased to 10 times that of the positively charged surface, the positive electricity will be 10 times denser than the negative charge, and consequently it will have 10 times the potential; in other words, 10 times the breaking-down power; so we see increasing the area of one of the inductive surfaces of a Leyden arrangement facilitates discharge between oppositely charged surfaces and produces in effect a similar result as diminishing the space dividing them. The experiments above described harmonize with the electro-magnetic experiment referred to in an earlier portion of this article, where a soft iron core was wrapped with two sets of convolutions of insulated wire; and, further, these experiments, I think, throw light on the *modus operandi* of a Winter's ring when mounted on the conductor of an electrical machine, the action of which, as far as I know, has never been clearly explained.

When considering phenomena associated with electricity of high potential, such as that developed by a Wimshurst influence machine, the part which the dielectric itself plays should not be overlooked. Atmospheric air, as is well known, is a very perfect insulator; but, at the same time, it is a mobile one, and capable of having currents set up in it; moreover, there is always more or less matter in a fine state of division suspended in it, which acts the part of a carrier, and by electrical attraction forms a continuous chain of more or less semi-conducting material, which helps to electrically bridge the space separating oppositely charged surfaces, and when the tension is sufficiently high, I am disposed to think actual electrolysis, or certainly something approaching to it, occurs. I have already pointed out that two platina plates, separated by an electrolytic liquid, are a Leyden arrangement with a dielectric of low resistance, requiring a low electric potential only to break up its organization, and that what we see actually occurs in such a Leyden arrangement enables us to comprehend what electricity of very high potential is striving to bring about in the matter composing dielectrics, such as glass or atmospheric air. In a Leyden arrangement, formed by platina plates in an electrolytic liquid, we have oxygen in a condensed form adhering to one of the platina plates, and hydrogen, also in a condensed condition, adhering to the second plate.

If with the aid of electrolysis we despoit platina in a fine state of division on the platina plates, so as to cover their surfaces with minute angular or pointed particles, the adhesion of the oxygen and hydrogen to the platina will be very much reduced, and the gases developed by the disorganization of the dielectric will leave the electrodes as fast as produced. I am not aware of any explanation of this well-known fact having been attempted. I, therefore, venture to suggest one which is simple and harmonizes with other observed electrical phenomena.

When smooth plates are employed continuous sheets of the condensed gases are deposited on them and held there by cohesion, but when the surfaces consist of numerous small pointed particles, these projections become coated with the oxygen and hydrogen not in continuous sheets, but in minute detached masses similarly electrified, electrical repulsion between them therefore occurs, and the cohesive force which held the gases in the case of the smooth plates is overcome. The smooth plates of continuous surface act analogously to what is observed when soft iron cylinders and solid metal rods are employed for electro-magnets and electrical conductors, and the platina surfaces consisting of numerous angular particles act analogously to what is observed when a bundle of fine iron wires and a bundle of copper wires are employed for electro magnets and electrical conductors. I attach importance to such harmonies which seem to me to stare one in the face, and are to be found in every direction if we only look out for them, because they act as finger posts pointing out the direction for research, and they also enable us to criticise and often to correct detached and imperfectly observed phenomena.

When we have two wires suspended in the air, and highly charged with opposite electricities, the atmosphere dividing them is in a high state of electrical polarization, and the oxygen and nitrogen probably also become condensed and adhere to the oppositely charged conductors much in the same way as that observed in the case of polarized plates in an electrolytic liquid. We have evidence of what is here suggested in the production of ozone wherever electricity is being developed by influence machines.

It is, of course, well known that polarized metal surfaces will develop currents by reaction, and a similar but much more rapid reaction must occur immediately after the discharge through the atmosphere of highly excited conductors, especially in those whose surface and length is great relatively to their mass, and I venture to suggest that what I have called attention to may help to account for some phenomena observed by Professor Lodge in the course of his experiments. Mr. Wimshurst informs me that if bare wires be suspended in the atmosphere, and charged by one of his machines in a darkened room, the surface of the wires will be seen to have become luminous throughout, and dotted over with innumerable bright stars, showing an active transmission of electrical energy is taking place through the atmosphere. He also informs me the same phenomena are observed, but in a less degree, with suspended wires coated with gutta-percha, unless the coating be a thick one, in which case no such appearance will be visible.

In the continuation of my remarks in the next issue of this journal, I propose to make the few comments on Professor Lodge's experiment which I feel permitted to do, and to say a few words on the subject of lightning discharges and lightning conductors.

Before making a few comments on Professor Lodge's lectures on the protection of buildings from lightning, I wish to correct an error in the last issue. A Leyden arrangement is there described whose negatively charged surface is assumed to = 100 and the positively charged surface on the other side of the dielectric to = 10, and I state the positive electricity will, under such conditions, be 10 times as dense as the negatively accumulated electricity on the larger surface. It is then stated in error that the positive charge will have 10 times the breaking down power. What I ought to have said was 10^2 times the force; for the power to break through the dielectric increases as the square of the density of the charge, harmonizing in this respect with the heating effect of an electric current passing through a conductor and also with the breaking down energy of a rifle ball whose penetrating power is as the square of the velocity; which is intelligible enough when we reflect that a rifle ball moving with twice the velocity of another one, will have twice the energy; and as it is traveling at

1. From the *Telegraphic Journal and Electrical Review* (London).

twice the speed, this two-fold energy is given out in half the time when an obstacle is met with in its path, and consequently the crushing effect or power to penetrate becomes increased four times.

The practical value of Professor Lodge's lectures, and also the articles on "Modern Views of Electricity," seem to me to have been impaired from too much importance being attached to hypotheses and speculations, which are reasoned upon as if they were established truths on which further hypotheses may be safely founded; the consequence is that the bases on which Professor Lodge develops his views become more and more involved as he proceeds, until the subject being dealt with gets involved in such an inextricable and complicated mass of purely hypothetical assumptions, treated as indisputable facts, that I find it almost impossible to follow the reasoning, much less to accept the conclusions ultimately arrived at.

The following passages, extracted from part ii., chapter 4, under the heading "Energy of Currents," will, I think, speak for themselves.[2]

"We must learn to distinguish between the flow of electricity and the flow of electric energy, they do not occur along the same paths."

Further on it is stated: "Electric energy is not to be regarded as pumped in at one end of a conducting wire, and as exuding in equal quantities at the other; the electricity does indeed travel thus, whatever the travel of electricity may ultimately be found to mean, but the energy does not; the battery emits its energy not to the wire direct, but to the surrounding medium; this is disturbed and strained, and propagates the strain from point to point till it reaches the wire and is dissipated. This, Professor Poynting would say, is the function of the wire; it is to dissipate the energy crowding into it from the medium which else would take up a static state of strain and cease to transmit any more. It is by the continuous dissipation of the medium's energy into heat that continuous propagation is rendered possible." "The energy of a dynamo does not, therefore, travel to a distant motor through the wires, but through the air. The energy of an Atlantic cable battery does not travel to America through the wire strands, but through the insulating sheath. This is a singular and apparently paradoxical view, yet it appears to be well founded."

Further on we read, "How does the energy of the distant dynamo reach the car in this case, not *via* the wire connector; not even *via* the underground conductor. It travels from the distant dynamo through the general insulating medium between cable and earth. Some little enters the conductor and is dissipated, but the great bulk flows on and converges on the motor in the car, which is thus propelled. All the energy of the conducting wire is dissipated and lost as heat; it is the energy of the insulating medium which is really transmitted and utilized." This curious complicated hypothesis, which may possess a charm for those who love to indulge in the scientific uses of the imagination, and think the province of the scientist is to theorize, is referred to again in part iv. under the heading "Radiation," not as an hypothesis, but as an established truth, or at least as a completely demonstrated theory. We are here told "It is a curious function this of the telegraph wire; it does not convey the pulses, it directs them. They are conveyed wholly by the ether at a pace determined by the properties of the ether, modified as it may be by the neighborhood of gross matter. Any disturbance which enters the wires is rapidly dissipated into heat and gets no further; it is the insulating medium round it which transmits the pulses to the distant station.

"All this was mentioned in part iii., and an attempt was made to explain the mechanism of the process and to illustrate in an analogical way what is going on. The point of the matter is—currents are not propelled by end thrusts like water in a pipe or air in a speaking tube, but by lateral propulsion as by a series of rotating wheels with their axes all at right angles to the wire surrounding it as a central core, slipping with more or less friction at its surface. This is characteristic of ether modes in general; it does not convey longitudinal waves or end thrust pulses like sound, but it conveys transverse vibrations or lateral pulses like light."

We are also told in an earlier portion of the article:—"We already know of a continuous incompressible fluid filling all space, and we call it the ether."

The existence of such an entity is, of course, purely supposititious, and all that can be said for it is that with the limited powers we possess it helps us in some sort to group together and explain observed phenomena which we otherwise could not so well do.

I venture to think, if the dictum that science is disciplined common sense be not overlooked, we shall come to a different conclusion from that which Professor Lodge seems to have arrived at. The resistance of a conductor, and the transmission of energy through it, harmonizes in every respect with the transmission of force through a hydraulic system, and given uniform lengths and pressures the energy transmitted, be it electrical or hydraulic, is directly as the sectional area of the conductors and the pipes; this being so, common sense would suggest that the energy in both cases is transmitted in a similar way, viz., through the interior of the conductor as well as through that of a pipe. Such a view receives further support from the fact that electrical energy also harmonizes with mechanical energy; its power to break down resistance, as already pointed out, following the same law as that which governs a rifle ball when in motion.

In taking leave of "Modern Views of Electricity," I cannot help expressing my conviction that if the views there contended for be generally accepted by the rising generation, we of the older schools, who have accomplished some electrical work in the past, will not just yet have to retire to a back seat.

I now pass on to the consideration of lightning discharges and lightning conductors. In the autumn of 1856 it was my good fortune to witness a magnificent storm in Asia Minor, when riding from Mudania to the City of Brusa, a distance of 20 miles.

The valley of Brusa, on the outskirts of which we traveled, is the bottom of an oval crater or basin, whose major and minor axes are about 25 and 12 miles respectively. Our road, for the most part was a succession of hills, which we ascended and descended one after the other, and which, I have no doubt, had been formed by the breaking down of the crater walls.

Between 3 and 4 P. M. we saw the storm beginning to gather in the distance, followed shortly afterwards by a vivid flash, which seemed to shake the ground over which we were riding; the thunder that followed reverberated between the rocks and the sides of the crater, producing a metallic rattle altogether unlike any thunder I have before or since had experience of.

A deluge of rain followed the discharge, and the storm gathered in force, reaching its maximum a little after sunset, and continuing in full force for some hours afterwards. When the storm was at its maximum intensity, the lightning flashes succeeded one another so rapidly as to light up the road and enable us to pick our way through the mountain streams produced by the heavy rain, and through which we had to pass.

The lightning discharges followed each other in sets of three with almost monotonous regularity, and were confined to a limited and apparently circular area. We were then too close to the base of the mountain range to be able to see where the lightning actually struck, but as far as I could judge, they all seemed to strike the summit of Mount Olympus, which was the highest point, and nearly 7,000 feet high.

I have already stated the discharges were in sets of three, the second and third discharges were single angular sparks, similar to what we are familiar with in England, only they were heavier and more vivid. The main discharge was, however, altogether different from any lightning I have witnessed elsewhere; it reminded me of a crooked trunk of a tree bulging out at the top, and was not unlike a waterspout. I have since thought it might have been a mass of rain drops, aggregated together by electric attraction, and illuminated by the flood of electricity passing through it.

The summit of the mountain would be immersed in cloud, and formed in all probability a focus where a very rapid condensation of the clouds into raindrops was occurring, the discharges having their origin in clouds higher still.

Some few weeks later I ascended Mount Olympus, the summit of which I found to be a crater in a conical hill, rising about 1,000 feet from a plateau; the diameter of the mouth of the crater (as nearly as we could estimate) being about two miles or somewhat more than this, and I think it very probable the area of discharge was limited to the size of the crater. One side of the crater was broken down to the level of the plateau, and there was a frozen lake at the bottom of the basin out of which ice-cold water was flowing, forming a stream, in which trout were swimming.

There are two other cases of lightning discharges I would briefly refer to; the first of these occurred in Hyde Park, and was witnessed by my father when he was a boy. The lightning struck a broad graveled path, and a cloud of fire was seen to rise from the path and meet the flash in the air, My father ran to the spot where he thought the lightning had struck, but there were no signs of it anywhere to be seen; the graveled path, however, had the appearance as if fine sand had been recently sieved over it, producing a smooth surface, and there was a smell of ozone. There is very little doubt that the finer particles of the gravel were raised from the ground by electrical attraction, that the lightning discharge diffused itself throughout the suspended matter, and dissipated its energy over a surface of ground instead of boring a hole.

The second of the two cases occurred in a meadow in the immediate neighborhood of Epsom Downs. On either side of this meadow there were garden walls, and the space dividing them I estimate as being about 400 yards. In a garden immediately behind the wall on one side of the meadow there was a low tree, the branches of which extended over the wall, and during a storm which happened on an "Oaks Day" a man took advantage of the overhanging branches for shelter. A lightning discharge struck the wall on the opposite side to the one against which the man was resting, and knocked out some bricks; it then passed horizontally across the meadow striking the man (who was killed

2. See *Nature* of November 3, 1887, and August 23, 1888.

on the spot), destroying brickwork behind him, and disappearing without leaving any further trace. I did not see this discharge myself, but I visited the spot some weeks later, after the damaged brickwork had been repaired, and what I have related was described to me by an eye witness. The subsoil of Epsom Downs is solid chalk, some hundred feet in thickness, and I think the probability is that the tree was growing where it was because there was a fissure in the chalk which enabled the roots to extend downwards and to obtain sustenance, that this fissure was the path of least resistance, and the man having unfortunately placed himself in its immediate vicinity, he suffered in consequence.

In the lecture delivered by Professor Lodge on March 10, 1888, the following passage occurs: "Perhaps the best protected building in the world is the Hotel de Ville, at Brussels, the hobby of M. Melsens; the whole system used in this building is excellent and theoretically perfect, so far as I know, in every respect."

Faraday used to say facts stood before all theory; and I came across a passage in an evening newspaper of June 26, 1888, containing the copy of a telegram received from Brussels, which I annex: "A thunderbolt fell this evening upon the Hotel de Ville. A fire resulted but it was soon extinguished. A good deal of surprise has been occasioned, for the building was recently provided with lightning conductors made on a supposed improved principle, and which scientists declared would render this fabric perfectly secure against lightning; but the result has proved the contrary."

To say the least, it is very unfortunate that a costly and supposed perfect system should so signally fail within a few months of erection; I feel somewhat curious to know what was the subsoil on which the building is erected, and how the earth connection was made. I am disposed to believe that the surging of currents through lightning conductors to which Professor Lodge gives so much prominence is much more imaginary than real; at the same time, I can readily imagine that numerous conductors over a building may, under certain circumstances, be a source of real danger where there is an imperfect earth connection, for the electricity will then diffuse and dissipate itself wherever it can, and it will find its way to the earth by numerous more or less imperfect channels. It may be through conductors inside, and where such conductors are small or angular, through the atmosphere or through gas fittings, etc., and such vagaries as breaking its way through chimney shafts to the heated soot inside, or through a wall to a gun or fire irons, or a water tank, is, I believe, to be attributed primarily to the want of a good connection with the earth, and not to oscillations or surgings of the current in a conductor.

If a Leyden jar be discharged into a metallic chain lying on a table, sparks will frequently be noticed to occur between the links and the table throughout the length of the chain, because the table is an imperfect conductor; and a similar, but more powerful action of this kind is very liable to occur, also, in the case of buildings having lightning conductors not perfectly connected to the earth.

I am, however, of opinion that it is possible to protect a building from lighting with comparative facility, whatever may be the nature of the subsoil.

The usual system of proceeding in the matter of the protection of buildings is radically wrong, but it is not the fault of the constructor of the lightning conductor, who does the best he can under the conditions in which he finds himself placed.

In the earlier of the two lectures lately delivered by Professor Lodge, reference is made to a lightning discharge which struck St. George's, Leicester. The electric current is stated to have passed down the vane rod halfway down the spire, "where it blew a ring of stones out and so dropped the top half of the spire neatly inside the bottom half."

It is not mentioned whether this church had any lightning conductor, but I presume it was so protected. My chief reason, however, for referring to it is that it reminds me of a somewhat similar case which occurred at Doncaster, which was described, if I remember rightly, by Sir Edmund Beckett Denison The vane rod of Doncaster church passed through the crown of the tower, protruding some feet inside below the roof and terminating in the air. The conductor outside was connected at its upper end to the vane rod above the masonry. The lightning discharge struck the vane rod, and the electricity passed through it into the inside of the tower, leaping from the lower end of the rod through the air to the conductor outside, knocking out blocks of stone and bringing down a mass of masonry much in the same way as occurred at St. George's, Leicester.

I have observed a similar sort of action to what occurred at Doncaster in several instances where telegraph wires have been connected to a multiple protector. Figure 4 represents a top view of a 4-wire protector and figure 5 the same in elevation. Supposing No. 1 line has been struck and the discharge has passed across the air space separating the end of the terminal block marked A to the earth block E, which will be indicated by the burning of the metal in the neighborhood of the air space, it will be observed almost invariably that burning has taken place also on the opposite side at the end of the terminal block marked B. In some cases more or less burning will be observed to have occurred at the ends of all the terminal blocks, the chief burning taking place in a pair of the terminal blocks on the opposite sides. I have by me an example which I have preserved in which six out of eight blocks have been burned, the chief burning occurring in two places on opposite sides of the earth block. What I have now directed attention to would seem to indicate that a lightning discharge, possibly by setting up motion in the atoms

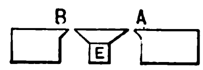

Fig.5.

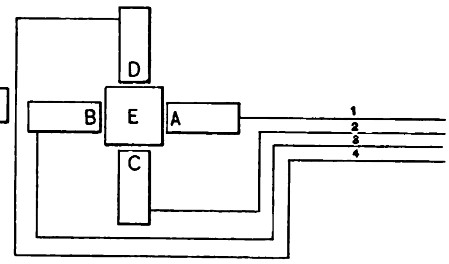

Fig.4.

composing the conductor, imparts momentum to them, and that the blow struck by the lightning at Doncaster threw the atoms of the vane rod into so rapid a state of motion as to break down the organization of the air and enable the electric discharge to pass through it and force out the masonry in its passage to the conductor outside.

To illustrate the views receiving the support of Professor Lodge, some very interesting experiments were performed at the second lecture, which are illustrated and described in the *Society of Arts Journal.*

The first of these is shown at figure 6, which has been copied from the *Journal*, containing the report of the lecture, and in reference to which it is stated: "The first form of experiment I have to describe is a very simple one. I call it the experiment of the alternative path; it consists in giving a Leyden jar discharge the choice between a certain conductor and a certain length of air, and in adjusting the length of air until it had lief take one path as the other.

"I am not aware that the particular mode of carrying out this simple experiment has any special significance; but to be definite, I depict the symmetrical arrangement I have most frequently, but not exclusively, adopted.

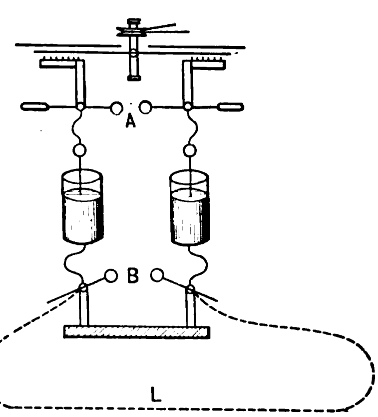

Fig.6.

"The knobs marked A are the ordinary terminals of a Voss machine, the jars stand on an ordinary wood table, and their outer coats are led to the discharger B, the distance of whose air space can be varied. The alternative path is shown by a dotted line. The discharge has to choose between B and L. Sometimes L is absent, and in that case the charging of the jars is quite well effected through the wood of the table; this is the advantage of having the jars imperfectly insulated. At the same time, the conducting power of the wood is too low to enable the jars to discharge themselves at all satisfactorily, unless the knobs, B, are within striking distance, or unless some path, L, is provided. The only discharge obtained at A, when both the paths, B and L, are absent, is a feeble spitting of intermittent and frequent sparking, very different from the loud report heard as soon as the knobs, B, are brought within striking distance. But it is not to be supposed that the B knobs must be as close together as the A knobs in order to permit complete discharge; on the contrary, the B knobs may be almost twice as far apart as the A knobs, and yet the charge may be complete and noisy.

"It will be understood that the two sparks occur together; a spark at A precipitates and is the cause of the spark at B; not *vice versa*, for until the A spark occurs there is not the slightest

tendency for a spark at B. The two B knobs are at the same zero potential, and may be touched with impunity except at the instant the flash occurs at A. Remember, the jars are standing on a common table all the time."

I confess that I cannot follow the reasoning from which it is concluded the spark, A, precipitates, and is the cause of the spark, B, not *vice versa*, but I pass on to the consideration of the results obtained, which I regard as much more important as well as more interesting.

Professor Lodge states: "The spark, A, was very loud whenever the spark was allowed to occur at B as well; but so soon as the discharge was compelled to traverse the alternative conductor, L, by putting the B knobs too far apart the noise of the discharge was much diminished, not merely because there is only one spark instead of two, but plainly because, for some reason or other, the discharge meets with considerable obstruction in the wire, whereby its duration is lengthened, and its noise, therefore, greatly lessened."

In the experiments described the length of the A spark was maintained at one inch, and as it was found convenient to measure the lengths in tenths of an inch, the A length was called 10.

The first alternative path consisted of 40 feet of No. 1 (B. W. G.) copper, suspended round the room by silk ribbon; and it was found the discharge refused to take this apparently easy path, and to persist in jumping the air gap, B, until the B knobs were separated 14.3 tenths of an inch, which was the critical distance, for when the B knobs were separated further apart the discharge chose the copper wire.

Now when a length of fine iron wire (No. 27, B. W. G.), whose resistance was 1,300 times as great as that of the copper wire, was substituted in its place, it was found that the distance separating the B knobs had to be reduced to 10.3 before the critical spark length was reached.

In other words, the discharge took place more readily through the fine iron wire than the much thicker copper one, a result (Professor Lodge says) that surprised him.

The summary of the results obtained with different sizes of copper and iron wires, the A spark length being 10 all the time, is given as below:—

Alternative paths.				Critical B spark lengths.
Stout copper wire,	No. 1 — R —	.025	ohms	... 14.3
Ordinary copper wire,	No. 19 — R —	2.72	"	... 13.4
Stout iron wire,	No. 1 — R —	.086	"	... 10.8
Ordinary iron wire,	No. 18 — R —	3.55	"	... 10.8
Thinned iron wire,	No. 27 — R —	33.3	"	... 10.3

Professor Lodge remarks in respect to the above: "The copper wires seem to obstruct almost equally, and the iron wires also obstruct equally among themselves, notwithstanding their very different diameters; but the coppers obstruct more than the irons."

Under the heading "Reason of the Enormous Obstruction offered by a good Conductor," it is stated: "Now what is the cause of all this astonishing obstruction offered by good conductors to the sudden rush of electricity?" One may express it in a popular way, thus: It is due to electrical inertia, or what is also called "self-induction." "A current cannot start in a conductor instantaneously any more than water in a pipe can start moving at full speed in an instant. Give the water a violent blow to make it move, it resists like a solid. The blow if very quick and violent may burst the pipe, but it will not appreciably propel the water, so in a manner is it with electricity. The flash occurs, and the conductor must either carry it off at once or not at all. There is no time to think about it, and the E. M. F. needed to overcome this inertia like obstruction is so great that a considerable thickness of air may be burst by it, and the discharge may flash off sideways to anything handy." Further on it is stated in this part of the lecture, there is another fact which it behooves us to be aware of. It is one to the importance of which the attention of scientific men has but recently been called. Experimentally it has been discovered by Professor Hughes, theoretically by Mr. Oliver Heaviside, Lord Rayleigh, and Professor Poynting; for though the necessary theory is really contained in Clerk-Maxwell, it required digging out and displaying. This has now been abundantly done, but the knowledge has scarcely yet penetrated to practical men; indeed, it has not yet been thoroughly assimilated by most physicists. The fact is this. When a current starts in a conductor, it does not start equally all through its section, it begins on the outside, and then gradually though rapidly penetrates to the interior. A steady current flows uniformly through the whole section of a conductor, a variable current does not. It is started first at the surface, and it is stopped first at the surface.

Remembering the rapidly oscillating character of an electric discharge, remembering also the fact that a rising current begins on the outside surface of a conductor, we perceive that, with a certain rate of alternation, no current will be able to penetrate below the most superficial layer or outer skin of the conductor at all. In the outer skin, of microscopic thickness, electricity will be oscillating to and fro, but the interior of the conductor will remain stolidly inert and take no part in the action.

Thus we arrive at a curious kind of resistance, caused by inertia in a roundabout fashion, and yet a real resistance, a reduction in the conducting substance of a rod, so that no portion except that close to the surface can take any part in the conduction of these rapidly alternating currents or discharges.

Now, notwithstanding the distinguished names mentioned, and who are credited with having theoretically and experimentally demonstrated that electricity (unlike water and other fluids) commences to flow through the outside of a conductor, I take leave to doubt it, and I express this opinion with the greater freedom, as I believe the correctness or incorrectness of these newer views can be determined by experiment. I may here state that, in conjunction with Mr. Wimshurst, I have tried some experiments to try and settle this point. These experiments are not yet completed; but they are so far positive, that they lead *me* to believe we shall at no distant date be able to confirm or refute what Professor Lodge seems to regard as determined already.

I have already said that I am not able to completely follow some of the reasoning having reference to the alternative path experiment, but I resist the temptation to say why I do so, because after all I should be expressing only my own views, and I do not set a high value on the views of any one (certainly not my own), unless they are backed by conclusive experiments, or harmonize with what we consider we really know. We can only reason from the known to the unknown, and in my own case, whatever scientific success I have been permitted to accomplish during the 56 years I have lived, I attribute solely to an early recognition of the harmony and parallelism which, as far as I can see, runs through *all* the phenomena of nature, and the simple fact which stares everyone in the face that be it a stream of people or a stream of water, the motion is observed to be more rapid in the centre would, if it stood alone by itself, be, in my opinion, an all sufficient reason for not believing that the flow of an electric current through a conductor commenced on the outside, and gradually penetrated to the interior, unless it was determined by absolutely conclusive experiments.

Although Professor Lodge has apparently convinced himself that electrical energy is not transmitted in a similar way to that of force through a pipe; nevertheless, when suggesting an explanation of the obstruction offered by good conductors to a sudden rush of electricity, he falls back upon a hydraulic simile.

The conductor forming the alternative path seems to me to somewhat resemble the musical wires which develop the lower notes of a pianoforte; these wires are in a state of tension, and would vibrate when struck at a rate that produces a comparatively high note, but being surrounded with spiral rings of heavier wire, the inertia which has to be overcome reduces the rate of vibration, and hence a lower note is given out.

When charging the jars in the alternative path experiment nearly the whole of the induction takes place between the inner and outer coatings of the Leyden jars at the earlier stage of charging, but as the charging proceeds, the induction which occurs through the air space of the A balls, and through the alternative path, increases; and as it is the air space separating the A balls where, practically speaking, the whole, or, perhaps, I should say, nearly the whole of the resistance occurs, the difference of potential is proportionately greater between the two A balls than at the two ends of the alternative path conductor, resembling, in this respect, a telegraph line of great resistance, in which the earth forms one half of the circuit. Now when the electrical potential becomes great enough to break down the resistance opposing discharge, the spiral rings of magnetism which are formed by the passage of the electric current through the wire, and which possess inertia, check the rate of the electrical pulsation much in the same way as the spiral metal rings surrounding a musical wire, and as the electricity set in motion refuses to wait, the air space separating the B balls, when not too far apart, opposes less resistance than the metallic conductor forming the alternative path.

I feel sure Professor Lodge would admit that further explanation is required to account for what was observed in his recorded experiments. Assuming, for example, that electricity commences to flow on the outside of conductors, why should not the current run down the outside of a copper wire as readily as outside an iron one; and why should copper wires of varying sectional area obstruct approximately equally, and also iron wires of different sectional area do the same? I myself am disposed to think that had the alternative path conductors been thickly coated with a good insulator the results obtained would have been found to be different from those recorded.

(To be continued.)

.... THE telegraphic system of England has been brought to the highest pitch of perfection. We have neither neglected the inventions of other countries, nor have we been chary of exercising inventive skill ourselves, and we have received our full meed of that reward which is always freely bestowed on a British government official—neglect and abuse.—*W. H. Preece.*

PROTECTION FROM LIGHTNING.[1]

In a previous article (see page 115 *ante Engineering*—page 496, Electrical Engineer), we dealt with the question of protection from lightning from the point of view of Dr. Oliver Lodge's recent researches, and the older experiments of Professor Hughes and Guillemin. As we mentioned at the time, the experimental results are to a certain extent contradicted by actual practice. If we were to be guided entirely by Dr. Lodge's experiments we might easily conclude that an ordinary solid lightning rod would afford but very little protection, or at least that it would not shield a building from side flashes which, if not very destructive, would be most alarming to the inmates. Now this is not in agreement with experience. In this country we have but little opportunity of finding out to what extent our conductors fulfill their supposed functions, for storms are not frequent and are never severe. But on the western plains of America, where atmospheric disturbances are on a much grander scale than here, the lightning rod has established itself as absolutely essential. It is applied to every building—houses, barns, and stables—so that a homestead literally bristles with points. In a country where the level plain stretches mile after mile without a hillock or a coppice, every prominent object becomes a discharging point through which electricity streams each time a thunder cloud drifts across the district. At night the ridge of an unprotected house may be seen aglow with the blue electric brush, while if it be provided with conductors, their points will absolutely flame with discharge. Often the electrified particles of air will furnish a path along which a flash will descend from the clouds. In such case there is no doubt where it strikes. The air of the house is filled with the powerful odor of ozone, and the flesh of the inmates creeps from the induced current which passes over the skin simultaneously with the discharge from the sky. But, in the great majority of cases, no harm is wrought. The electricity gets safely to ground through the conductor in spite of the self-induction of the rod.

Rods of different shapes and metals are employed, and practice has failed to award the palm to any particular form or material. Cylindrical and flat rods, both of iron and of copper, have been found efficient when properly erected, and, on the other hand, both shapes and metals have failed when not suitably fixed. Dr. Lodge believes that an iron conductor is better than a copper one, founding his opinion on experimental evidence deduced from the length of spark which can be obtained in an air shunt circuit forming a by-pass to a metallic circuit traversed by an electric discharge, figure 1. He argues that the greater the resistance offered by the metallic conductor L, the greater will be the air gap which the spark will leap to relieve itself by another path, B. The figures obtained were 1.43 in. for stout copper wire, and 1.08 in. for similar iron wire, showing apparently that the iron wire opposed the least resistance to the discharge. That may be so, but we would point out that the attempt to measure sparking distances to the hundredth of an inch is unsatisfactory unless done with precautions which are not mentioned by Dr. Lodge. If an

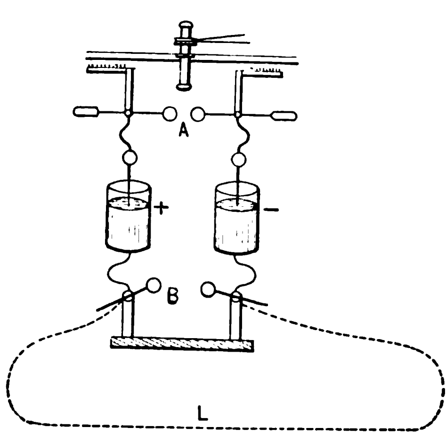

Fig. 1.

air resistance is to be made the standard of measurement the air must be absolutely free from dust, and each spark must be taken through a body of air not previously submitted to the discharge. The need of these precautions must be self-evident to all who have experimented with statical electricity. No two successive sparks in the open air follow the same path; they appear to leap from dust particle to dust particle, seeking for stepping-stones to bridge the gap. Again, the sparking distance between two terminals rapidly increases after the first two or three discharges, and when a path has been formed through the air, the gap may be increased very considerably. In the face of these facts, sparking distances measured in hundredths of an inch in the open atmosphere have but little quantitative value, unless they can be reproduced time after time with certainty. Dr. Lodge does not tell us upon how many experiments he bases his opinion that iron rods are better conductors of discharges than copper ones.

The fortuitous character of the electric discharge is well exemplified by the following experiments, which have been made by Mr. James Wimshurst, at our suggestion. As is well known, Mr. Wimshurst's laboratory is equipped with influence machines of a size and capacity transcending all others, and from which sparks up to 15 in. in length, and of enormous quantity, can be obtained. He has, therefore, the means at command to carry on experimental investigations in the region of atmospheric electricity on the largest scale, added to an experience of many years in which the successful production of electrical phenomena has been a constant

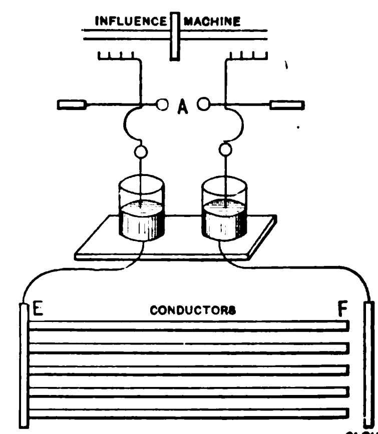

Fig. 2.

study. All this valuable apparatus, and his more valuable assistance, Mr. Wimshurst is always ready to put at the disposal of scientific workers, and our thanks are due to him for the aid he has furnished us in the following investigation into the comparative security offered by different kinds of lightning rods. The experiment, or rather the series of experiments, had for their object in the first place to determine to what extent an electric discharge would exercise a selective action if a number of paths were presented to it. It was certain that it would display some preference, for if a wooden rod and a copper rod be placed side by side, lightning will follow the metal path and not the wooden one. But will it select a copper rod in preference to an iron one, or a flat rod in preference to a round?

The arrangements adopted followed those of Dr. Lodge up to a certain point. In both cases it was the sudden or impulsive form of discharge that was used. This was for two reasons; first, because it is believed that this kind of flash is far more dangerous to buildings than that which has a path prepared for it by induction; and second, because it is practically impossible to get an induction spark to leap into a rod unless it be capped with a ball, which is a most serious departure from the conditions of actual practice and vitiates the conclusions which may be drawn. The impulsive flash occurs during a thunder storm, when a cloud high in the air suddenly discharges into a lower one, and this again discharges to earth. In such a case the electricity strikes for the nearest conductor. But if a charged cloud stands over a building for some time before striking then it draws electricity from the earth, and this produces currents of electrified particles of air from all the points of the roof towards the cloud. If the building be provided with a conductor the charge in the cloud may be actually neutralized in this way, or there may be an upward flash from the rod. In any case the probability of the discharge being confined to the rod is far greater than with an impulsive flash. In the laboratory a brush is seen on the point of the rod, and the electricity leaks away faster than any machine can supply it.

Figure 2, shows the arrangement adopted by Mr. Wimshurst, in the first series of experiments. The terminals of the influence machine were connected respectively to the insides of two groups of Leyden jars, each group consisting of one two-gallon jar and three one-gallon jars. The outsides of these sets of jars were connected respectively to two plates, E, F, between which the rods were arranged, one plate representing the earth and the other a cloud. The rods were laid horizontally upon glass supports, and were separated from the imitation cloud at one end by distances commencing at 1 in., and gradually increased inch by inch up to 5 in. At each stage 20 successive sparks were discharged from the cloud towards the conductor, and it was noted which rod was selected. The following rods were employed:—

1. 5 ft. of No. 14 B. W. G. copper wire.
2. 5 ft. " " iron wire.
3. 5 ft. of copper riband of equal section to No. 1 copper rod, ⅜ in. wide.

1. *Engineering* (London).

4. 5 ft. iron riband equal in section to No. 1 copper rod, ⅜ in. wide.
5. 5 ft. of No. 14 B. W. G. iron wire inclosed in a thin copper tube.

When the distance from the cloud to the rods was 3 in., and their other ends were placed to earth, the following results were got:—

The copper rod was selected 6 times.
" iron " " " 5 "
" copper strip " " 5 "
" iron " " " 3 "
" copper covered iron was selected 2 times.

The distance between the ends of the rods and the cloud was then increased to 4 in., and the following results obtained:—

The copper rod was selected 4 times.
" iron " " 2 "
" copper strip " 13 "
" iron " " 3 "
" copper covered rod was selected 2 times.

With a 5 in. distance the results were:—

The copper rod was selected 13 times.
" iron " " 5 "
" copper strip " 0 "
" iron " " 2 "
" copper covered rod was selected 2 times.

It would be unwarranted, we think, to draw any conclusions from these experiments except that the course of the discharge is determined mainly by atmospheric conditions, and that a metallic conductor, if it be of sufficient size to carry the current without destruction, may be of iron or copper, and round or flat, as may be most convenient. If we attempt to reckon up the totals of the three experiments we find that the copper rod shows the best score and the copper strip the next best, but a comparison of the behavior of the copper strip in the second and third experiments shows that this method of estimation is very risky.

Four other experiments were made with bad earths, that is, there was an air gap at the foot of the rods, as well as one between the rods and the clouds. The former was made successively ¾ in., 1 in., 1½ in., and 2½ in. Eighty-one sparks were passed and an account kept of the rods struck. The following are the aggregate results of the four experiments:—

The copper rod was selected 11 times.
" iron " " 20 "
" copper strip " 20 "
" iron " " 13 "
" copper covered iron 17 "

If we attempt to draw any conclusion, it is that an iron rod and a copper strip stand on an equality. But an examination of the detailed results, which are too long to give here, shows that the selection was very erratic. One rod would be struck several times in succession, and then would be entirely neglected for a time, and we are forced to the conclusion that atmospheric conditions had a great deal to do with the path chosen by the spark. When the issue was narrowed by using only two rods at a time rather more definite results were obtained, and the spark exhibited some preference for the round rod over the strip. But it was apparently the form rather than the metal which influenced the selection.

When witnessing these experiments the conclusion which presented itself to the mind was that a good conductor might be made either of iron or copper, and be flat or round as was most convenient for structural purposes. If a perfectly uninterrupted metallic path of a size which will not suffer from the heating or deflagrating effect of the current be offered to a discharge, the electricity may be relied upon to follow it. But it is most important that it shall be uninterrupted, and this condition is difficult of attainment with a lightning conductor. The earth contact forms a break which needs to be very carefully bridged to render it as efficient as the remainder of the circuit, and if it be not thus bridged fine-drawn distinctions between different sections of rods become mere waste of words. For instance, if the iron and copper rods mentioned above be laid side by side, and one be connected metallically to the earth plate while the other is kept ¼ in. away and the gap bridged by a piece of thick brown paper soaked in water, the spark will select the metallic circuit every time. It does not matter whether the copper or the iron be the metal with the bad earth; it is always shunned and the other rod is followed. Mr. Wimshurst has made some experiments with earth plates, which are most instructive, as showing the very ample surfaces which they require to have. A model house was taken with a flat metal roof 8 in. square. The house was divided by floors into three stories, and in the upper room there were metallic brackets, representing gas and water fittings, projecting from the walls. Down the side of the house ran a copper lightning rod which could be put to earth in various ways. The gas and water pipes were also connected to earth. Over the house stood a copper plate representing a cloud. This plate was connected to the outer coating of one Leyden jar, while the outer coating of the other jar (figure 2) represented earth. In the first instance the conductor was connected metallically to earth and successive sparks were passed into it from the cloud. There was then no sparking between the metallic roof and the gas and water fittings, either when the roof was connected to the conductor or when it was not. Apparently all was safe, although, as we shall show later on, the plan of connecting metal roofs to the lightning conductor is not without danger. An artificial earth was then interposed between the bottom of the conductor and the Leyden jar, by aid of a porcelain dish partly filled with damp garden mold. A layer of earth about 1 in. thick was first placed in the dish, and on this were laid two metal plates, each measuring 7½ in. by 3¾ in. The adjacent long edges of the plates were separated by 2½ in. Over the whole another layer of earth, 1 in. thick, was laid, and the entire mass firmly consolidated by pressure. One plate was connected to the lightning conductor and the other to the outside of the Leyden jar, the discharge having to pass through the mold between the edges of the plates. The degree of humidity of the mold was in excess of that ordinarily existing in garden ground at a depth of 4 feet or 5 feet. The influence machine was then worked and sparks passed from the cloud to the conductor in rapid succession. In every case a part of the discharge leaped from the roof across 1½ in. of air to the gas bracket and got to earth that way. When the roof was connected to the lightning rod the current had no difficulty, of course, in reaching the gas fittings. But when this connection was broken, the spark had first to leap from the rod to the roof and then from the roof to the gas pipe before it could find the easy path it required.

These experiments put in the strongest possible light the need of having a very large surface at the earth plate of a lightning rod. Twenty-eight square inches were provided for the escape of a spark which must have been infinitesimal compared with a flash of lightning, and yet they were utterly insufficient for the purpose. The discharge was ready to dart out of the rod wherever an easier path was to be found. If it had been a real flash it would have displaced the coping or rent the wall in its path to the metal roof. The damage did not occur at the earth plate. A little disturbance there might be viewed with unconcern, but it is quite another affair to have a flash of lightning hunting round the inside of a house to find a road leading to earth. Yet if an impulsive flash enter a rod this result will certainly happen if the ground contact be insufficient. Most people who have dabbled in electricity have unexpectedly proved this on their persons in attempting to discharge a Leyden jar. If one end of the usual discharging tongs (without the glass handle) be applied to the outside of the jar, and then the other end to the knob, no effect is felt by the operator. But if, in manipulating the upper arm, he inadvertently allows the lower arm to leave the surface of the jar by a fraction of an inch, then he gets a share of the contents of the jar, which teaches him a lesson of caution he never forgets. He is just in the position of a man standing beside a lightning conductor with a poor earth contact.

In towns the underground pipes lie very temptingly to hand for connection to conductors, and we do not see why they should not be used. The water pipes are no doubt better for the purpose than gas pipes, as there is generally sufficient leakage from them to insure a good deal of damp earth in their vicinity. But any pipes which are jointed metal to metal may be used with impunity. It may be that the electricity will have to travel a considerable distance before it all escapes, but there is no fear of its entering the neighboring houses. The electrostatic capacity of a system of mains is so great that it is impossible for it to be charged to a dangerous potential by a single flash, even supposing there were no leakage. In a previous article we referred to the fact that the immense lead roof of the dome of St. Paul's was insulated at one time, and yet held all the flashes it must have received without harm, and it is certain that long lengths of pipes would act in a similar way. Of course they must be metallically connected with each other; joints of india-rubber or white lead would interpose very considerable resistance to the current. Failing pipes, an earth plate must be used. It cannot be too large, and it must be placed in ground which is damp in the dryest summer.

It is an established practice to connect all metallic roofs to lightning conductors, and Dr. Lodge recommends it. Since the date of his lecture, however, there has been a notable example of a building on the continent, in which the roofs were so joined, being struck by lightning and set on fire. Now Mr. Wimshurst's experiments, detailed above, have shown that when there is a bad "earth" to the conductor the lead roof serves to convey the current to all parts of the building, so that a person standing in the upper story runs the greatest possible risk of being struck, particularly if his body offers a convenient path to a water or a gas pipe. This is more particularly true if the lightning rod be connected to the roof. If it be not connected then there is the possibility that the discharge may find an escape without entering the roof at all. In one experiment the earth contact was represented by a break in the conductor, ⅝ in. long, filled with a tube of wet paper tightly rolled round the two separated ends. When an impulsive flash leapt from the cloud there were always sparks inside the house, a part of the current escaping by the imitation gas pipes every time. When the earth contact was good there were no sparks, but there is reason to think that the upper floor of the house was

even then a dangerous locality, as will be seen from another experiment.

When a thunder cloud stands over a district it attracts a charge of opposite name in the earth and buildings beneath it, and when the cloud discharges itself this induction charge is set free. Now it is argued in the case of a lead covered house that this charge may spark off and do some damage, and therefore a path should be provided for it by connecting the metal to the lightning rod. Further, Dr. Lodge considers that a lead roof may play a very useful part from its electrostatic capacity. He likens it to an air vessel or a pump, and suggests that it receives and stores a part of the flash and then gradually emits it, thus reducing the rush in the conductor, and preventing the pressure in it becoming so great that sparks will flash off from intermediate parts of the rod. If we endeavor to verify this experimentally by connecting the cloud over the model house to the inside of a Leyden jar, while the foot of the conductor (which must terminate in a knob) is connected to the outside, then we find that by presenting a knuckle to the roof we can draw a spark every time the cloud discharges. This happens whether the roof be connected to the conductors or not, but the spark is the sharper when the two are joined. If, however, under the latter condition one finger be placed on a gas bracket while another is presented to the roof, a comparatively severe shock is felt. Under the conditions of an actual storm this shock might be very serious. For instance, a man washing his hands in a fixed basin, with a metal waste pipe would be in a perilous position if under a lead roof connected to a lightning conductor. Again, a house with composition gas pipes would be very likely to be set on fire if a flash struck into them, for the metal would melt and the gas be ignited. The danger can be minimized by connecting the roof to the ground by its own conductor, quite independently of the lightning rod. When this is done in the model house no shock is felt, even when the hand is interposed between the roof and the gas bracket. As a matter of fact, it would be difficult to find an instance of an insulated roof, for the down spouts generally are in metallic connection between the covering and the ground. Of course, they cannot be relied upon to make good "earth," but if the roof be only protected from a flash entering it, either directly or from the lightning rod, any charge it may get inductively will not greatly matter.

The outcome of these experiments is to restore our confidence in the ordinary lightning conductor, which had been a good deal shaken by Dr. Lodge. They show that the causes of failure are to be sought rather at the ends of the rod than in the conductor itself. At the bottom it is most essential that a perfect earth contact should be secured; without this a lightning conductor is a gratuitous source of danger. At the top there must be a point at each stack of chimneys or other projection, for it is not safe to rely upon a large area of protection from a single terminal. Metal roofs should be kept away from contact with the lightning rod, and so should gas and water pipes. If not they provide an open road for the distribution of lightning within a house. At the same time, additional security is gained by providing all large masses of metal with independent conductors so situated that they cannot easily become paths for electricity from the clouds. Thus, if by any chance the current should overflow from the main conductor, it will soon find a ready path, and will be prevented from darting backwards and forwards, trying first one piece of metal and then another. If these precautions be observed there should be little danger from lightning, whether the conductor be round or flat, or be of iron or copper.

ELECTRIC LIGHTING IN AMERICA.[1]

BY PROFESSOR GEORGE FORBES, F.R.S.

Having since the last meeting of the British Association had occasion to pay two visits to the United States, and while there to study very carefully the systems of central station lighting in vogue, and also to compare what was being done there with what was being done here, and being, further, able to compare the state of central station lighting in America as it is at present with the condition it was in four years ago, when this association visited America, I felt it was a sort of duty I owed to the association to bring before it some account of what I had seen, believing it would be especially interesting at the present moment, when there are signs of a very great determination on the part of the public in this country to have electric light supplied to them from central stations. At the same time I felt considerable diffidence in bringing before you the facts which have been collected—not in the least because there is any want of facts, but by reason of their number, which renders it difficult to make a proper selection of the points likely to be of interest to the members of this section.

In the first place, it has been often stated, and one cannot help commencing remarks of this kind by repeating, that enormous progress has been made in central station lighting in America. At the moment one lands, one is struck by it; and when one lands, upon returning to England, one is equally struck by the dimness of the lighting in our streets. In America, there is not a single town with which I am acquainted where you can walk in the streets at night without seeing very many arc lamps. I am not simply speaking of influential towns like New York, Philadelphia, and Boston, but of the most out-of-the-way places in the most distant states, where gas has never penetrated. There electric lighting has fixed its position, and it is being used frequently. Not only has the electric light been adopted in these remote towns, but other developments of electricity have followed. As an illustration of the kind of places to which electricity and electric light have found their way, I may mention that I have a paper here published in a village in Alaska, one of the least developed of the territories of the United States, and the same number of this paper, which treats of the introduction of electricity in a scientific manner, treats also of the advisability of passing a law for the expulsion of Indians from the city at nine o'clock every evening.

At the time I was attending the Electric Light Convention at Pittsburgh last February, it was estimated that there were then 300,000 arc lamps lighted from central stations in America. The progress of arc lighting of late years, however, has not been so striking to an Englishman as formerly; the arc light was firmly established when the British Association visited America four years ago. The progress which has struck us all latterly has been the progress in incandescent lighting. At the same time—I am speaking of February of the present year—it was estimated that there were 2¼ millions of incandescent lamps in use in the United States; and the rate of manufacture has increased enormously, to my knowledge, since that short time ago There are four or five manufacturing places in the United States at this moment, each capable of turning out 10,000 incandescent lamps every day, and I have no doubt that the annual production at this moment is to be counted by millions. Of incandescent central stations, there are two classes, one of which is the three-wire system, in which a continuous current is supplied to the main conductors over a town, and the lamps are connected by branches to the system of positive, negative, and intermediate mains. That is the system which is so largely adopted in all the Edison stations; it was the Edison stations which interested us most in 1884, and they have continued to advance and have developed the three-wire system to a very great extent indeed.

But I feel quite sure that the greatest progress that has been made in central station lighting in America since the association visited it has been by the work which Mr. Westinghouse has done in that country. One of Mr. Westinghouse's agents in passing through Europe saw the experiments, which had been made by Messrs. Gaulard and Gibbs in this country in the use of alternating currents to distribute the electric light; by means of this system an alternating current of very high tension could be passed along the streets over conductors of very thin diameter and very cheap to construct, and at the consumer's premises this high tension dangerous current could be reduced in tension by means of an induction apparatus called a converter and passed into the house at a harmless pressure suitable for the ordinary incandescent lamps.

And here I may say that I never fail to take any opportunity which presents itself to me to say what I feel with regard to the energy and determination with which Messrs. Gaulard and Gibbs, in spite of the most adverse criticism which was universally passed upon their first attempts, persevered and continued to improve their invention and eventually proved to the world that it was possible to have a commercial system by means of these converters.

Mr. Westinghouse, on seeing this system, took it up, and the result is that he has established, in the course of a very few years, an enormous business in central station work. It is now a possibility in America—not a possibility merely, but a thing of daily occurrence—for a town to write an order for a central station, which has to be sent out at ten days' notice. They do not order a dynamo, set of conductors, and other apparatus all independently, but complete central stations are being sent out at a steady and uniform rate. In December of last year the manufacturers of incandescent lamps drew out a long list of the number of lamps being used in different parts of the country, and I have abstracted from that list some notes which show that at that time Mr. Westinghouse's alternating current system was supplying 153,285 lamps, occupying 152 distinct plants, and 42 of these had plant for more than 1,000 lamps. At the present moment they have set up 110 central stations with 191,000 lamps.

It has been said that in this country we do not go ahead so much as they do in America, and various reasons have been suggested to account for this. Professor Ayrton's most admirable reason seems to go a long way—namely that there are two definitions of inertia, the English, which is that inertia is a resistance to motion, and the American, that it is a resistance to stopping. But I must say that in electric lighting we certainly have been stopped a great deal by what I might almost call the iniquitous Electric Lighting Act. And I regret extremely, in

1. Read before the British Association for the Advancement of Science. September 10, 1888.

the interests of the public and of electric lighting generally, that an act has been passed this year which has not yet put electricity on the same footing as gas. This is a matter for extreme regret to all those who have the ultimate benefit of the electric lighting industry at heart, for that Act will delay the due recognition of the value of electric lighting.

But I must say that I do not think the Electric Lighting Act is the only thing which has delayed our progress, because I see that in electric traction and other developments of electricity also the Americans have gone ahead with great energy, and I certainly do not put it down to want of capacity on the part of our inventors, for I find that the best dynamo machines are all designed originally in England, and the best arc lamps there are are to be found in England; but with inferior machines and lamps in the states, I have noticed that they are determined, as long as they have something which they know will work well, to make it work, and be ready in the meanwhile to take up something else. I think, therefore, that it is not in the inventors that we have to look for goaheadedness, but to men of capital who are technically instructed. I think it is technical instruction among the moneyed classes that has developed electrical engineering so much in America of late years.

I will now try to describe some of the leading features of the Westinghouse central stations which I visited, and perhaps this may be of use in helping us to draw some conclusions as to the lines in which we are to develop electric lighting in our own country. I do not in the least wish to say that the American arrangements are the best. In many points I see objections, and many where I should wish to see improvements; but we have in the system which I am going to describe a thoroughly successful working arrangement, and although we in this country may not adopt all the points of such an arrangement, still I feel that it will be of use to us to realize what is being done on the other side. It is a curious thing, for example, that in America there is no work hardly being done with accumulators. There is an example where we have led the way, as compared with the Americans. I was struck with the fact in 1884, and still more in the present year, that accumulators do not seem to work in the American atmosphere; at any rate, people have been importing numbers of accumulators, and yet they are not recognized as the satisfactory apparatus we have come to regard them as; they are looked upon there as being as uncertain now as they were with us four or five years ago.

The Westinghouse system, then, chiefly depends upon the apparatus which has been called by the names secondary generator, transformer, or converter; "converter" is the term generally adopted in America. This is simply an induction apparatus with two coils, a primary and a secondary. The primary coil, in contra-distinction to the ordinary Rhumkorff induction coil that we have known so long, is of high resistance, with a large number of turns on the primary and a small number on the secondary which goes to the lamps. The alternating current produces induction in passing through the primary, which reacts on the secondary, thereby producing a current of low tension going into the houses. The primary coil and the secondary are completely separated, and when properly constructed, it is quite impossible that the high tension current can ever reach the secondary circuit, so that the consumers of electricity have nothing to fear from the dangerous current which is distributed from the central station.

A central station contains furnaces and boilers, engines, alternate current dynamos, exciting dynamos, switch-boards, testing instruments, repairing shop and stores. The scheme of arrangement of the mechanical and electrical parts is generally the same in every station.

The wires led out from the station are carried generally on poles as feeders to the separate districts. The converters are generally attached to the outside wall of the house to be supplied; but they are often attached to the poles carrying the feeders. They are sometimes placed inside the houses. The secondary wires inside the house, to which the lamps are attached, are laid in the usual manner, and are connected to the secondary poles of the converter. The dynamos are run day and night without cessation. Charges are made by contract or by meter.

We hear a good deal here of the impossibility of running machinery day and night without breakdowns, and I cannot help rather endorsing the opinion I heard universally expressed in America—that this fear has been enormously exaggerated in this country. When we see our huge 10,000 to 15,000 h. p. engines crossing the ocean, performing their work for days and weeks without breakdown of any sort, it seems absurd to expect that where we are able to subdivide our power, as in a central station, there should be any serious breakdown in a properly organized system. As a matter of fact I assure you that in America plants which have been run without accumulators have been going on for years and years, and it is a matter of the utmost rarity for an accident to arise of sufficient importance to stop the general lighting of the district. The Edison central station in Pearl street, New York, which has been running many years, has, I believe, only once broken down, and that was an accidental occurrence due to too much current being turned on on a foggy day, and the experience of other central stations is to the same effect. The general view in America is that there is no danger of a breakdown ever happening in a properly organized station.

It happens that in the department of furnaces and boilers there is much of special interest in many of the Westinghouse stations. This arises from the fact that over a great part of Western Pennsylvania the fuel employed is the natural gas obtained from the wells in that region, and carried in pipes to considerable distances. But this is a feature so peculiar to the district that it requires only a short notice here.

The gas, with its due proportion of air to produce the high temperature of a Bunsen burner, is admitted by pipes with a sufficient number of nozzles into the combustion chamber. Here the burning gas passes over a mass of bricks with ventilating spaces, and thence through the tubes of the boilers. The gas is nearly free from carbon, and the hydrogen, which is paramount, undoubtedly weakens the iron of the boilers; but practice shows that this action does not go far, and the iron acquires a final condition in which it does not deteriorate, but seems capable of indefinite use.

In the best stations the admission of gas and air to the furnaces is regulated by means of a valve controlled by a lever, which in its turn is subject to the pressure of the steam in the boiler. This automatic regulation is very perfect, so that the attendance of one man to the boilers and furnaces of a station with several thousand horse-power is quite sufficient.

As to steam engines there is no need to say much, for I do not think the Americans can teach us anything about making steam engines. But there are some points in connection with the class of steam engine used which I think are of importance. A great deal has been said about the desirability of having central stations furnished with large, powerful, slow-running engines which are economical in the consumption of coal. Practical experience, however, has decided the question for the present exactly in the opposite manner. It is found to be more economical and safer to have a number of dynamos in each station, each driven by a separate engine of high speed, the power being transmitted through a belt and with no countershafting. About the rights of this question there cannot be the slightest doubt. It has been proved over and over again by experience. At first sight it does not seem probable that a number of independent high-speed engines should be more economical or safer than a single large engine, say of the marine type. The explanation lies in the special conditions of central station lighting. Without dwelling upon the great loss of power due to countershafting with the large engine, it is only necessary to observe that the maximum load in a lighting station is many times as great as the average load. Thus, if the single engine be adopted for the maximum load, it is working underloaded during the greater part of the 24 hours. The consumption of steam in proportion to power developed is very high, and the engine is under these circumstances not an economical one. With the independent engines, on the other hand, none of them need at any time be working much under its best load, and when the load increases other engines and dynamos can be switched in, and they are thus always working at or near the most economical conditions.

It has been found from actual practice in electric light work in identical central stations that 20 per cent more work is required in the case when countershafting is introduced.

It has also been proved from the experience of numerous central stations, that during a considerable number of hours in the night the load on the engines and dynamos is only one-eighth part of the maximum load.

For these reasons it is found most economical to use with each dynamo an engine whose most economical load is something like 20 per cent under the maximum load. Waste of steam is far greater with underloading than with overloading.

Another advantage of this system is that there is abundance of time for the inspection of engines and dynamos. The station is easily added to. A breakdown in an engine or dynamo does not stop the working of the station. There is one other factor of safety to which attention must be drawn. One of the most annoying accidents in an electric lighting plant is that due to a short circuit on the mains. In overhead work this often happens by the falling of broken telephone or dead wires upon the mains. In this case a small independent engine is pulled up and no damage is done. With the large engine the dynamo grinds on, and unless the cause of short circuit is burnt up, the dynamo is destroyed, or at any rate the whole of the working is put out of gear.

Now I have a word or two to say about dynamos and converters, the actual apparatus which are used in America. I attribute a great deal of the manufacturing success of American electric lighting plant to this, that they fix upon the types of machine that they are going to make, and then lay down machinery which will enable them to produce those types cheaply, and having thought out the system thoroughly in the beginning, they do not require to make a completely new type of machine for every order that comes in. They are then able to manufacture their machinery cheaply, and in such a way that every part is replaceable.

At this moment I think if I had to choose between two dynamos of which one was a little better than the other in efficiency, but the other of which was manufactured in this way, I should be very much inclined to lean in favor of the one which was made by machinery, and of which all the parts were interchangeable, and of which I could get any one of the parts by return train by telegraphing for it. The convenience of such a machine is obviously great.

I have, for the benefit of those who are electrical engineers and manufacturers, thought it might be of interest to put down some facts in connection with the three types of alternating current dynamo machines made by the Westinghouse company. There are three types, one for 650 lights, another for 1,300, and another for 2,600. The voltage of all is the same, 1,050. In this country there has been a tendency to use on the primary circuit a higher tension than that, 2,000 volts. In the Westinghouse system they use 1,000 volts at the converters, and 1,050 is developed by the machines. The local pressure is reduced in the same proportion as has been done most generally in Europe, that is to say, in the ratio of 20 to 1. The 1,000 volts in America is reduced down to 50 volts in the lamps, and in this country the 2,000 volts has been reduced to 100 volts at the lamps. And here there is a question opened which must be decided immediately in the central stations which are going to be put down in this country, whether you are going to take the full advantage, as Mr. Westinghouse does of being able to carry your high tension current in the mains.

The advantage is that you are able to save copper to a very great extent indeed, whether you use 1,000 or 2,000 volts, and then, as Mr. Westinghouse argues, we are able to use lamps of only 50 volts instead of lamps of 100 volts; that he looks upon as the greatest advantage he has gained by the introduction of the Gaulard and Gibbs system. We all know that the higher the voltage of the lamp the shorter its life, and a 50 volt lamp is a far more perfect thing than a 100 volt lamp. We are greatly troubled by the expense of lamps compared with their life. That is an expensive item in the supply of electricity, and, a 50 volt lamp being far more economical, is it not desirable to follow the American plan and use the lower voltage? I am sure that electrical engineers generally will see that there is a point worthy of their serious consideration in this question.

It may even be said that we are all to go still further and reduce the voltage a great deal more. Of that I am less certain; but there is another point which will occur to electrical engineers, whether it is not desirable to use the lamps which Mr. Bernstein has been perfecting, of very low voltage, placed in series. At present one of the most serious difficulties in introducing electric light for domestic purposes from central stations, is in the cost of wiring houses. Now, if we place our electric lamps all in series, the cost of wiring will be very much diminished, and it becomes a question whether this is not the best arrangement. In that case the primary coils of our converters would be put in series in the same way as they were originally in the Gaulard and Gibbs system. We shall then be doing what they were striving to do when they chose the series arrangement, namely, not by having the two primary terminals inside the house at a difference of potential at 1,000 or 2,000 volts, which would be dangerous, but no two conductors of greater difference of potential than about 50 or 100 volts. If at the same time we use low voltage lamps, we shall get a longer life than even Mr. Westinghouse has obtained. It seems to me that there are grave reasons for considering most seriously the question of arranging all our lamps in series and the primary coils in our converters in series also.

But I am not here to put forward suggestions about what we may probably do in England, but only to tell you what they are doing in America, wishing at the same time to guard myself from saying that they have the best arrangements in every possible point.

The construction of the Westinghouse dynamo is pretty well known in this country, and it is needless to speak of it.

I think we are probably all agreed that the old type of alternating current dynamo, such as the Siemens, has probably seen the end of its days. One of the chief difficulties seems to be that when you have such a large number of coils revolving between the poles you are obliged to make a considerable clearance, and that causes you to use up a great deal of power in magnetizing the field magnets. Mr. Westinghouse makes a very small clearance and in that way uses up only 2 % of the maximum power.

The Westinghouse company makes those types of dynamo, of which the following particulars are of interest:—

Dynamo No.	i.	ii.	iii.
E. M. F.	1050	1050	1050
Current	35	65	130
Resistance (armature) at 30° C.	.76	.37	.15
" (fields) " " "	14.5	7.0	3.6
Weight of wire in armature	17	30	60
" " fields	420	..	..
Total weight	4800	9000	..
No. of lights	650	1300	2600

The No. iii, has an armature about two feet diameter and two feet long. It has 16 poles, and runs at 1,000 revolutions per minute. The armature plates have each six large holes for ventilation and lightness. The weight of armature is 2,000 pounds. The insulation is mica and copal varnish, which is found to be infinitely superior to shellac or any other material tried.

The converters used by the Westinghouse company are of five sizes, called by the numbers i., ii., iv., vi. and viii. The following table gives particulars about them. The size of wire is on the B. and S. gauge:—

Converter.	i.	ii.	iv.	vi.	viii.
No. of lights	5	10	20	30	40
Wire on primary	25	22	19	17	16
" " secondary	11	8	8	8	7
Turns on primary	900	700	560	480	400
" " secondary	45	35	28	24	20
Resistance of primary	48	21.9	9.9	7	5
" " secondary	.04	.043	.0197	.0176	.0107
Weight finished (lbs.)	50	60	95	..	160

Thickness of iron plates — .006 to .0065 inch.
" " paper insulation — .0025.
Number of plates in a No. 8 converter — 1350.
The iron used is Welsh Taggard iron.
50° C. rise in temperature is allowed in the converters.

In this country the tendency is to make converters much larger; it has even been suggested that they should be made of thousands of lights. But for ordinary use in houses the Westinghouse system is the simplest, more especially as we find that it is necessary to wire the houses in such a way that they will suit our meters, which at present do not go over a range of from one lamp up to a thousand lamps, nor even up to hundreds of lamps, and if we find that our range is suitable up to 40 lamps it is very desirable to wire the houses in such a way that there are not more than 40 in the circuit of a meter indicating 40. For this reason Mr. Westinghouse has limited his converters in this way.

There are some points well worthy of attention in regard to converters. In the first place, by the use of only 1,000 volts, a far cheaper converter may be made, and thus a great saving may be effected in the plant required for a house. Then, again, there is the rapidity of alternation. In the Westinghouse plant there are 16,000 alternations, 8,000 complete periods, per minute. In this country the tendency is to make the alternations less than that. The quantity of iron you put in your converters depends on the number of alternations; the greater the number of alternations the less iron is required, and you are therefore able to use smaller converters. I do not know whether or not there are objections upon other grounds to a high number of alternations. The only objection that occurs to me is that, while the construction of the dynamo sometimes becomes a little easier, it also takes a little more space.

Mr. Westinghouse asked me to make some tests for him on the efficiency of his converters. It has been supposed that converters have not a high efficiency when working at half load. I may mention that the efficiency varied slightly in the different types, owing to the proportions of iron being greater in some types than in others; but at half load in some cases we were able to get an efficiency of 95 per cent,, which is a splendid result, and I think a greater efficiency than most people have been supposing was to be attained. I do not think that in actual practice there is an average waste of 10 per cent. in the use of converters, when they are properly designed. The formulæ which regulate the construction of converters has been given by me in the *Journal* of the Society of Telegraph Engineers and Electricians, February, 1888.

I may also say that Mr. Westinghouse has in his lamps 70 per cent. of the power given to the belt by his engine, which is a very good return for converters and alternating dynamos, showing that the new alternating current machines are much superior to the old one, which gave about 70 per cent. efficiency.

The wiring is nearly all overhead in the states. The wire used is called simplex wire, and is made by a firm in Boston. It is very carefully prepared, and is, I think, beginning to be known in this country, and gives satisfaction.

For underground work Waring cable, which is lead-covered, is used with complete success. I am informing you now of what is being used, and used successfully, and what may be used successfully by us in this country; but you must not suppose that I hold that these arrangements are the best.

Now comes a most important point of distribution. Ought the conductors to be massed in one heavy main, with all the dynamos feeding it, or ought the main to be much subdivided, with, perhaps, several to each dynamo? or ought we to take an intermediate arrangement? The experience of the Westinghouse

company leads to the subdivision of mains as far as possible, because a short circuit on any main then endangers only one dynamo.

I have often been asked the question whether alternating dynamos can be worked in parallel. They can, when they are fully loaded down almost to half load, but below that they do not synchronize. Great subdivision of the mains has been found in practice to facilitate largely the working of the central station.

There is one thing that will probably be spoken about in the discussion which will follow my remarks, and that is the high speed of the Westinghouse dynamo. I think there is needless objection to high speed by engineers in this country. If we have a uniform cylinder of iron revolving, I have no objection to any rate of speed so long as I know the shafting will not give way.

I think it would be desirable that some of the gentlemen present should give us their views as to the desirability of using a high or low number of alternations, high or low voltage in the primary, whether 50 volts will be desirable in use, and also as to whether subdivision of mains is desirable, and whether the converters should be supplied have only a limited number of lamps, such as 40 or 50.

I have now attempted to give you a general idea of working central stations in America on the system which has been most fully developed of late years. It is the result of a great amount of careful work, and in the work of the immediate future in England I am sure that English engineers will be benefited by the large practical experience which our trans-Atlantic cousins have collected.

SKETCH OF THE ELECTRICAL PAPERS IN SECTION A, AT THE RECENT BATH MEETING OF THE BRITISH ASSOCIATION.[1]

BY PROFESSOR OLIVER J. LODGE, F. R. S.

Some talk of Isaac Newton, of Euler and Clairaut
Of Kepler and Copernicus, and old Galileo;
But of all the mathematicians
There's none who can compare
With the row dow dow de dow dow dow
Of the British Engineer.

THE above verse may be said to strike the keynote of the recent British Association meeting at Bath, as it appeals to an outsider. The note was struck both in the presidential address and in the address of the president of section G, and it has been further emphasized, no doubt beyond the meaning of either president, by an instructive leading article in the oldest engineering journal. The following extract is from the *Engineer*, of date September 7:—

"Sir Frederick Bramwell's address is mainly a pleasant discourse on the part which the engineer has played in the world, and is principally remarkable as a well-constructed refutation of the preposterous pretentions put forward by some men of so-called pure science. * * * The theme is so congenial that we feel no keen desire to criticise what Sir Frederick Bramwell had to say. Our only quarrel with him, indeed, is that he did not go far enough, or press his arguments with sufficient insistance. Possibly it was impossible or impolitic to push his arguments home. * * * No one, however, knows better than Sir Frederick that the world owes next to nothing to the man of pure science. In another page we give an abstract of the address, from which it will be seen how carefully Sir Frederick avoided the utterance of a word that might give offense. But we are not tied or bound by any consideration of this kind, and we should be lacking in our duty did we not assert whenever the occasion for assertion arises, that the engineer, and the engineer alone, is the great civilizer. The man of science follows in his train."

Meanwhile, in the quiet and peaceful atmosphere of section A, some good work has been done, and in the calm temperament engendered by such work and by the assured feeling of progress in insight and knowledge, there is a disposition, I doubt not, to grant to the engineer all the credit he, or others for him, can possibly claim, and not to resent even such a singular tone as is sounded in the above quoted leading article. There is, after all, some excuse for a good deal of self-glorification when the society transforming consequences of an engineer's labors is regarded; and yet one would not be surprised if one learnt that great individual engineers—such for instance, as the builder of the Forth Bridge—were among the most unassuming of men.

I propose to give a brief account of such of the communications to section A, as may be expected more particularly to interest the readers of this journal. It should be always clearly apprehended that when one man gives an account of another's work that other is in no sense responsible for or bound by what is said. It ought to be absurd to have to point this out, but experience shows that it is not unnecessary; and it is especially necessary to call attention to the fact in connection with a hasty report of a great number of papers, written without notes and without the respective authors' knowledge or supervision. However carefully one may attempt the task some errors are bound to creep in, and were it not that in process of time all these papers will be published in authentic form by their writers, one would not be justified in making the attempt. But persons not able to be present may find even a partially correct account of what went on at the meeting better than none at all.

First, then, the section was happy in having for its president a man exhibiting an altogether exceptional combination of qualities —profound knowledge, great originality, mathematical and experimental skill both of the first order, quickness of comprehension, and a ready wit. The address with which he opened the business of the section was not unworthy of the man. Its subject was that greatest of all physical subjects, "The Ether," and it largely consisted in a glorification of the quite recent experiments of Dr. Hertz in Berlin, whereby Professor Fitzgerald shows that the existence of an ether is raised out of the rank of a very probable hypothesis, which it has long been, into the domain of demonstrated facts. He hints also that certain outstanding problems concerning the structure and properties of the ether can most probably be answered by a further discussion and repetition of experiments like those of Hertz. Our engineering friends ought not to sneer at the prominence given to such a refined abstraction or hypothetical figment as the ether may seem to some of them to be, for it is by its means they drive all electric motors, it is it they use in dynamos and transformers of all sorts; it is the ether which transmits their signals, whether telegraphic or telephonic; and, though this may appeal to them less forcibly, it is through the action of the ether that mankind is enabled to see. Not to mention the as yet incompletely verified hypothesis that it is of ether that engineers and all other material substances are composed.

On Friday morning, the serious electrical business of the section began, and Professor Rowland exhibited his most recent photographs of the solar spectrum, obtained by a yet more nearly perfect concave grating which he had just completed. The photographs exhibited at a former meeting by Professor Rowland had far eclipsed anything previously accomplished; but those now shown were still better, and represent an extraordinary stage of perfection. They are by far the most magnificent things of the sort ever seen. The special appliances in Professor Rowland's laboratory at Baltimore for this work are so perfect and convenient, that the whole solar spectrum can be photographed on an immense scale in the course of a morning. Terrestrial spectra, such as that of iron, can be photographed for purposes of comparison at the same time on the same strips of glass.

It may be hastily thought that such a subject belongs primarily to optics, but it is not so. Ingenious mechanical devices and optical theorems are made use of in obtaining the result, but the influence of the result is more felt in other sciences. The existence of such a standard of wave lengths and permanent measurable records of atomic vibration reacts upon several of the sciences. It reacts upon astronomy by furnishing a statement of the present condition of sun and stars, with which future observations may be readily compared; upon chemistry by exhibiting the relations among the vibration numbers of the elements, whereby hypotheses as to the construction and compound nature of our elements may be tested; and it reacts upon electricity by affording us some knowledge of the precise way in which the ether is disturbed by electric oscillations in the substance of the atoms as well as by the motions of electrically charged atoms themselves.

Lord Rayleigh followed, with an account of an exceedingly delicate and difficult experiment on the question whether an electric current through a liquid influences the velocity of light therein. It is well known that when an electric current flows through an electrolyte an actual transfer of matter accompanies it—two opposite transfers, in fact, as evidenced by the continuous appearance and escape of the travelers, one at each electrode. It is also known by a refined experiment of Fizeau, confirmed by Michelson, that when a beam of light travels down a stream of moving matter its speed is slightly increased, whereas if light travel against a stream of water it is slightly retarded. These things being so, it may be held as probable that whenever the two ions taking part in an electrolytic current differ in momentum a slight effect may be exerted on the velocity of light traveling with or against the current. But then, according to the calculations of Kohlrausch, confirmed by some experiments of the present writer,[2] the speed of the electrolytic ions is extremely small, the quickest being 30 microns per second, or about four inches an hour, for an applied slope of potential of one volt per centimeter.

The effect of such a creep as this was not what Lord Rayleigh looked for. It was quite within the range of possibility that the existence of an electric current in an electrolyte should so disturb the ether inside it as to produce quite a notable change in its index of refraction. Were such an effect discovered it would be a distinctly new fact, not taken account of or even rendered probable by existing theories, and it is very well to have the question experimentally examined, and to a certain extent set at rest.

The method adopted was a beautiful interference arrangement of Michelson, whereby a beam of light is split up into two halves,

1. From the *Electrician* (London).

2. Birmingham British Association Report, 1886, p. 393.

which are sent along a certain route, or circular tour, in opposite directions are then recombined into one again at the point whence they originally split off, and are examined by a magnifying eye-piece. The result is a set of interference bands more or less well defined. Tubes containing dilute sulphuric acid supplied with an electric current are then placed along the route taken by the two half beams of light, so that one-half the beam will be helped and the other half hindered by the current, if it produce any effect at all. The thing looked for is to see if the interference fringes shift along microscopically when the current is supplied, stopped, or reversed. The result is negative, and by considering carefully how much of an effect could have been certainly perceived if it had existed, the definite statement is made that a current of intensity one ampere per square centimeter through dilute sulphuric acid does not affect the velocity of light in its own direction by so much as one part in 13,000,000, or by 15 meters per second.

There are two ways of experimenting. One is to order expensive and highly polished optical banks and other apparatus from an instrument maker; the other, to rig up an arrangement with odd bits of glass, cement and portions of telescopes. The born experimentalist adopts the latter plan; considering beforehand where exactness and steadiness is essential and where it is unnecessary, and accommodating his means to his end with forethought and localized precision. It is by this latter mode of experimenting that the just quoted result has been obtained.

A couple of papers by the present writer followed. One, on the "Measurement of Electro-magnetic Wave-Lengths," the other, on the "Impedance of Conductors to Leyden Jar Discharges." The point of the first paper was to bring forward a case of electric resonance whereby pulses rushing to and fro along a couple of long insulated wires of certain length, synchronized with the known oscillations or alternations in a discharging Leyden jar circuit connected to them. The experiment is thus analogous to an acoustic experiment known by the name of Melde, wherein a tuning fork attached to a long stretched silk string throws it into synchronous vibrations when everything is properly adjusted. And just as the length of the sympathetic string is half the wave length of the sound emitted by the vibrating fork, so the length of each wire in the electrical analogue is half the length of the ethereal waves emitted by the discharging Leyden jar. These waves being essentially light, except that they are much too long to affect the retina. If Hertz had not simultaneously been experimenting in very similar directions, the interest of these experiments might have been greater, but as it is they are perhaps mainly interesting as affording a confirmation of the theory of Kirchhoff, Thomson, and Heaviside, regarding the rate of propagation of telegraphic impulses along a wire. These pulses travel at a speed always a trifle under the velocity of light—under certain perfectly known conditions very much under; but in the most favorable case of two thin parallel wires, transmitting exceedingly rapid oscillatory disturbances (the case of the above described experiment), the velocity of the pulses is, according to theory, exactly the velocity of light; and so it comes out in the experiment. The length of the waves emitted by the Leyden jar circuit can be calculated directly one knows the capacity of the jar and the self-induction of its circuit; the length of the waves sent along the wires can also be observed experimentally; the two determinations are found to be in close agreement.

The following data may be of interest:—

A microfarad condenser, discharging through a good conducting coil of one sec-ohm, gives a current alternating 159 times a second, and emits ether waves 1,200 miles long.

A gallon Leyden jar, discharging through a stout wire suspended round an ordinary sized room, emits waves between 300 or 400 yards in length, its current alternating at the rate of a million per second.

A pint Leyden jar, sparking through an ordinary pair of discharging tongs, gives a current of 15,000,000 alternations per second, with ether waves some 20 yards in length.

An ordinary electrostatic charge on a conducting sphere two feet in diameter, if disturbed in any way, will surge to and fro at the rate of 300,000.000 vibrations a second, emitting waves a yard long.

Electric charges on bodies of atomic dimensions, if able to oscillate at all, would vibrate thousands of billions of times a second, and produce ultra-violet light.

The maximum amplitudes of current given in these several cases can also be stated if the initial difference of potential be given. For instance, the microfarad case charged to a volt will have a current amplitude of one milliampere; the pint jar case charged to give an inch spark will give a discharge current of maximum strength 2,500 amperes.

The second paper by Professor Lodge, "On Impedance of Conductors," has to do with the obstruction offered by conductors of different sizes and materials to sudden rushes of electricity. A series of experiments on the E. M. F. needed to force the contents of a Leyden jar, under given circumstances, through a wire of measured length and thickness arranged in the form of a circle (a single turn about a yard and a half in diameter being usually employed) are briefly described. The numerical results obtained are then compared with the theory of Clerk-Maxwell and Lord Rayleigh, and are found to be in very satisfactory agreement.

The noteworthy thing about these sudden rushes, or violently alternating currents, is that they keep wholly to the outer surface of a conductor, and accordingly the obstruction they meet with has next to nothing to do with either the specific resistance or the magnetic properties of the material. A number of quantitative determinations have been made which will be published elsewhere.

The reason why these alternating or rapidly-varying currents keep to the outside of a conductor is merely because the outside affords the easiest path. If they penetrated its substance like steady currents do, it would have to be magnetized and demagnetized in concentric cylinders by them, and this would cause delay and obstruction. By keeping to the outside they avoid having to do this. It is true that they thereby throttle the conducting area open to them very considerably. They would meet with much less frictional resistance if they permeated the whole sectional area of the wire, but then, for these very rapid variations, frictional resistance is of far less consequence than the inertia-like obstruction of varying magnetization; and, on the whole, they find it better to escape the inertia by keeping to the outside, even at the expense of a throttled and highly resisting path. The whole thing is a compromise, and currents of slower rates of alternation will penetrate deeper, always taking the course which reduces total obstruction to a minimum, until we come to steady or slowly-changing currents, to which the inertia effect of magnetization matters next to nothing, while friction matters just as much to them as to any of the others; these, therefore, will flow through the whole cross-section of the wire with complete uniformity. Regret was expressed both by Lord Rayleigh and by the President that Mr. Oliver Heaviside, who had done so much in the theory of these matters, was not present to join in the discussion.

Next came three papers by Sir William Thomson, the third of which, as connected with the foregoing subject, it is convenient to take first. Its title is, "Five Applications of Fourier's Law of Diffusion, illustrated by a Diagram of Curves, with Absolute Numerical Values," and its subject-matter is the accentuation of the analogy and complete mathematical equivalence existing between the different kinds of diffusion, so that the method suitable for treating one enables problems in the others to be solved. The best known cases of diffusion are:—(a) *The diffusion of substance*, as when a heavy salt solution creeps up from the bottom of a vessel of water until it becomes, in a century or two, thoroughly mixed; or when a scent diffuses in the air; (b) *the diffusion of momentum*, as when motion is transmitted from one part of a viscous fluid to the rest, this being the process by which tea can be stirred, and by which winds and whirlpools are brought to rest some time after the exciting cause has ceased; (c) *the diffusion of energy*, better known as the conduction of heat, a frequently quoted consequence of its laws being the gradual penetration of an alternating disturbance deep and deeper into the substance of a conductor—as, for instance, the diurnal and annual fluctuation of temperature finding their way down into the crust of the earth, so that at a certain depth one could find evidence of heat waves six months behindhand; (d) *the diffusion of electric potential* in the conductor of a submarine cable, worked out long ago by Sir William Thomson as one of the problems to which Atlantic telegraphy gave rise, and by the solution and complete understanding of which rapid submarine telegraphy became practicable; and (e) *the diffusion of electric currents* in the substance of a homogeneous conductor.

It is this last kind of diffusion which is evidently most interesting Sir William at the present time, and he does justice to Mr. Oliver Heaviside's labors in connection with it.

I have been saying above that a very rapidly alternating current keeps to the outside of a conductor, just as a very rapidly alternating force applied to the surface of water in a trough (say by means of a flat board lying on it made to vibrate horizontally) would only succeed in moving the surface water; but this is not a complete account of the matter. When an alternating cause acts at a surface its effect penetrates in waves of diffusion through the mass, dying out according to a certain law of decay. If the alternations are slow the depth of penetration may be very great, as, for example, heat waves in the earth's crust; if they are excessively quick the depth of penetration may be very small indeed. And so for any given frequency of alternation, there is a specifiable depth at which the substance of the medium will appreciably take part in the action, and beyond which no noteworthy effect is produced. The problem, then, is to determine this depth for such rapidities of oscillation as are most common in practice.

The modern supply of alternating currents for secondary generators would seem to have a frequency of something like 150 complete alternations per second, and Sir William Thomson reckons that the depth to which these disturbances penetrate into the substance of a copper conductor is about 8 millimeters, so that portions of the conductor beyond this distance from the surface are almost useless. Hence manifestly conductors for powerful alternating currents should be hollow tubes or flat bars, or separated wires, and the useful thickness of flat copper bars

adapted to carry the present rapidity of alternating currents will be about 6 millimeters, or, say ¼in.[1]

Of the other two communications of Sir William Thomson it is not easy to give an intelligible account without introducing technicalities; but inasmuch as they afforded a text for a great deal of discussion, both in and out of the section, I must try and give a general notion of what they are about. Their titles are, "A Simple Hypothesis for Electro-magnetic Induction of Incomplete Circuits: with Consequent Equations of Electric Motion in fixed Homogeneous or Heterogeneous Solid Matter," and "On the Transference of Electricity within a Solid Conductor." It is not often that the public are admitted to the genesis of scientific ideas, or are allowed to witness a development of opinion going on before them. But in the presence of Sir William Thomson this is no new thing. At his Baltimore lectures a few years back the whole University turned itself with enthusiasm into a research society, and many germs of discovery flourished or faded during the few weeks those lectures lasted. Then, the main topic was an elastic-solid theory of light. Now, we may observe a further step, and without abandoning an elastic-solid theory, which in some form or another is a necessity, Sir William is assimilating, and criticising, and extending, Maxwell's electrical theory. Finding in it certain apparent excrescences and redundancies, he seeks to lop them off and keep only that which is essential. Long-standing students of both Thomson and Maxwell join in, and throughout the meeting there is, among the *dii majores*, discussion and keen competition to see through the fog of symbols, to disentangle their real physical meaning, and to find a right and proper position for the half lopped-off apparent excrescences of Maxwell.

The main point under discussion relates to the mode and rate of propagation of electrostatic potential as compared with electro-magnetic potential. Electro-magnetic disturbances correspond to shearing strains in an elastic solid; they travel through the ether with the velocity of light—the lines of magnetic force spreading broadside on—and about them there is no difficulty. Difficulties begin with the propagation of electrostatic displacements, which correspond to the disturbances possible in an ordinary fluid; longitudinal not transverse disturbances having to do with incompressibility instead of rigidity, disturbances which in ordinary matter we call *sound*.

Suddenly confer upon a conductor an electric charge: in all directions there is experienced a rise of potential equal to $\frac{Q}{r}$. How did that potential reach any given place? Was it by end thrust, or pulse of longitudinal compression, like sound? and, if so, at what rate did it travel? Maxwell assumes the ether to be absolutely incompressible, and, if so, the rate of propagation of disturbances corresponding to sound waves in it is infinite. Longitudinal pulses are not, strictly speaking, *transmitted* at all through a medium of infinite incompressibility, they are simply felt at all distances instantaneously.

That ether is *enormously* incompressible is proved (so it seems to the writer, and he has probably acquired it insensibly through the pores from Maxwell) by an experiment which is best called the "Cavendish experiment," referred to (in a poverty-stricken form) in French books by the name of Biot, and popularly known as the "outsidedness" of electrostatic charge. It is also proved (again to the mind of the writer) by the fact established by Laplace that gravitation, if transmitted at all, is transmitted with a velocity too great to be ascertained at present, and certainly much greater than the velocity of light. But that anything is *infinitely* incompressible is an assertion which it is impossible to make on the basis of any experiment whatever.

Accordingly, Helmholtz has taken into account the possibility of a slight compressibility, and has generalized Maxwell's equations by the introduction of a symbol, k, expressing this compressibility. Helmholtz's equations, therefore, enable this quantity to have any value which experiment may hereafter determine for it, including the possible value 0, which would reduce his theory to Maxwell's again. It is the value of this constant, k, the compressibility of the ether, which the president referred to in his address as hoping to be able to deduce by a further analysis of the experiments of Hertz.

But now, directly a possibility of compression and a finite velocity for longitudinal waves is introduced into the ether, a long outstanding difficulty in the theory of light—a difficulty from which it was hoped the electrical theory would be free, though the ordinary elastic-solid theory is not free—at once makes its appearance. This is the old friend (or enemy) of undulatory theorists, the wave of longitudinal compression, or the "pressural wave," as it is sometimes called. Indeed, in the form of a pressural wave - the instantaneous transmission of a thrust to infinity —it must come in even to an incompressible ether, if the transmission of electrostatic potential occurs by end thrust.

This electrostatic potential is denoted in Maxwell's equations by the symbol Ψ, and so the attempt to get rid of it and do without it in the general equations of an electro-magnetic field was referred to by the president as the "murder of Ψ." Many deaths, and many bringings to life, this unfortunate symbol suffered in the course of the week, and I would not like to say that its fate is even yet decided. On the last day of the meeting Rowland and Fitzgerald seemed to come to an understanding, but whether Sir William will coincide with it, or will upset the whole thing once more, remains to be seen. As they put it the matter is now like this: The propagation of electrostatic potential does not go on by end thrust at all; it is not really analogous to a pulse of longitudinal compression, though it is apparently and superficially so; and accordingly its rate of propagation depends not at all on the compressibility or incompressibility of the ether, a question on which it has nothing to say one way or the other. An electrostatic field is not developed *sui generis*, but is always the consequence of a previously existing electro-magnetic one, which, on subsiding, leaves it as its permanent record.

Plainly, an electrostatic field cannot arise without the motion of some electricity, either with or through a conductor. Now, whenever electricity moves, it at once has magnetic properties—its motion generates a magnetic field. When the motion ceases the field at once subsides, and in subsiding it may produce a succession of diffusing and dying away induction currents in neighboring conductors; or it may, if the circuit be an incomplete one, leave a permanent vestige of itself in the dielectric as a field of strained ether—this state of strain being what we call electrostatic potential, and the field being familiar to us as an electrostatic field.

Generating it in this way, all distinction between rate of propagation of electrostatic and electro-magnetic potential vanishes, they both travel together with the velocity of light; or rather, the thing which travels is the magnetic potential, and its permanent effect *in situ* is the electrostatic potential.

Thus, once more, the difficulty of a longitudinal or pressural wave disappears from the electrical theory of light, into which it had seemed to intrude itself, and Ψ is left to enjoy "a long and useful career," though it is not permitted an infinite or any other rate of propagation in its own proper nature. The question of the incompressibility or compressibility of the ether thus remains unanswered, and, as it would seem, unanswerable, by any such experiments as those of Hertz, or by any experiments on the rate of transmission of electrostatic potential. If any one asks how soon will the pull of a suddenly electrified body be felt at a distance, one may answer, "As soon as the charging spark is seen." But if it be asked at what rate electrostatic potential travels, the answer is that it does not travel, but is generated *in situ* by the subsidence of a magnetic potential which travels with the velocity of light.

It must be understood that the last word has by no means been said on these great problems, and that what I have here written must be digested with salt. It is proper also to record the conviction expressed by the president that most of these refined points would probably be found mathematically treated somewhere in the writings of Mr. Heaviside.

On Saturday, the principal communication was one from Professor Hicks on "A Vortex Analogue of Static Electricity," wherein an idea concerning the ultimate nature of electrostatic attraction is promulgated, which promises to have the most vital influence not only in electrostatics, but in electro-chemistry and theories of valency in general. These points came out most strikingly, not on Saturday, when the paper was read, but at a later stage on the Wednesday following. It so happened that, by reason of the section meeting on this Wednesday an hour earlier than usual, several of the authors failed to turn up, and the sitting threatened to collapse. The section, however, promptly requested its president to fill up the time by telling them the present state of the controversy concerning the elimination of Ψ from the general equations of the electro-magnetic field—the equations concerned with electro-magnetic wave propagation. Professor Fitzgerald at once responded by telling us, not about Ψ, but about Hicks; calling attention to a few ideas which the vortex analogue of static electricity had suggested to him. Professor Hicks joined in with fresh suggestions, and in about 10 minutes of to and fro conversation the most splendid possibilities of future theory, avenues of light permeating the ultimate facts of chemistry, as the ramifications of a lightning flash permeate the atmosphere, were opened up. One may attend many British Association meetings without hearing a "desultory conversation" such as this; one may organize discussions and endeavor to secure them, but they are by no means certainly so procurable. Like genius they must arise spontaneously, or not at all, and woe be to the president who nips them in the bud.

The main point in Professor Hick's communication was a statement of the way in which, under certain circumstances, a hollow vortex may arise between two bodies which are being separated in a perfect fluid. These hollow vortices, or whirls, or cyclones, differ from ordinary vortices in having as their core a stagnant portion of fluid, or an empty space, and their motion is what is known as irrotational—that is, there is no spin at every point of the liquid. The consequence of the centrifugal force of the whirl is a reduction of pressure at the centre, as meteorologists well know is the case with atmospheric cyclones, and as anyone may see in an ordinary plug wash hand basin. The effect of this reduced pressure at the axis of the whirl is to enable the cir-

1. These numbers are not authoritative.

cumambient fluid to press the two bodies towards each other, and thus to give rise to a measurable attraction. The mathematical laws of hollow vortices are found by Hicks to be such that they distribute themselves over the surfaces of bodies precisely like lines of electrostatic force, and they urge the two bodies together with a force varying inversely with the square of the distance. Thus they obey the laws of electrostatic attraction, and every hollow vortex may be called a line of force. Their ends abutting on the surfaces of the bodies will be analogous to, and will represent, the phenomenon called "electrostatic charge;" and however far the bodies are separated these "charges" remain constant. The aspect of the whirls being opposite, as seen from either body, their ends may be styled positive and negative respectively.

If a third body is introduced between the original pair, some of the whirls separate into two, with their ends abutting on the intermediate body, which thus acquires equal positive and negative charges; it is subject to induction. And so on. All the main phenomena of static electricity may be imitated by the behavior of these hollow vortices in a perfect fluid, and they take the place of lines of force.

Now comes the chemical application. The circumstance which is essential for the generation of these hollow vortices, when two bodies are separated from contact, is that during contact they shall be connected by an ordinary vortex filament with its ends abutting one on each body. Such a filament causes throughout the medium a state of rotation which results in the generation of a hollow vortex at the point of contact as soon as that contact is broken. When the distance between the bodies (which may now be called atoms) becomes considerable, the original vortex filament is so pulled out as to exert very little effect, and it may be neglected; but the hollow vortex generated by it increases in energy as the bodies are separated against its attractive influence, and retains its cross-section unimpaired.

The original vortex filament joining the atoms in contact thus corresponds to what chemists call a "bond" or unit of chemical affinity. There may easily be more than one such bond, perhaps as many as six, joining two bodies; it is a question of stability, and the limit of number can be worked out by vortex mathematics. The hollow vortex which makes its appearance when the atoms are separated corresponds to the electrostatic charges and lines of force existing between the monad constituents of a dissociated molecule.

If there are two bonds with the same sense joining two atoms in contact, then when they are separated two hollow vortices will be found between them, corresponding to the two units of electrostatic charge which are found on a dissociated dyad atom. Any one hollow vortex may easily split up so as to distribute its ends properly over the surfaces of the bodies as they are further separated, but its essential properties are unaltered by fission; and the exact dependence of the electrostatic charge on the original number of dissociated bonds is an evident re-statement of Faraday's law of electrolysis.

But there is the possibility that two original bonds should whirl in opposite directions, and in that case they would neutralize each other's effect at the point of contact and generate no electrostatic charge at all when the bodies are separated. Such a mode of combination may correspond to what chemists style "molecular," and atoms dissociated from such molecules would be intractable to electrical influence—the compound would not be an electrolyte.

There is no need for the original vortex filament to reach across from one body to another; its ends may quite well abut both against the same body, and in that case we shall have a self-satisfied pair of units of chemical affinity. Another body coming into the neighborhood of such a looped bond may open it out; and it may do so in either of two ways; it may break it in two in the middle, thus linking itself to the first body by two bonds of opposite sign; or it may let one end slide from the original body on to itself, thus effecting a monad style of combination, giving rise to electrified atoms when dissociated.

Furthermore, of the self satisfied or looped bonds possessed by a body there may be a considerable number—possibly a very great number; it is again a question of stability to be worked out, but not yet worked out, by hydro-dynamics; and the loops may some of them be long, so as to project a good distance from the body, while some may be quite short and close to its surface.

The long loops will correspond to the important bonds able to intersect and combine with another atom at a considerable distance—that is, at a high temperature; while the shorter and closer loops can only be expected to act at close quarters, *i. e.* when the temperature of the substance is low. Thus it may turn out that at very low temperatures all manner of complex aggregations are possible.

At first sight it might seem as if high temperature favored chemical combination, but that is a mistake. High temperature is often necessary to break up existing molecules, and so to enable fresh and often more powerful combinations to form; but high temperature is a dissociating and expanding influence *per se*, and it is at low temperatures that the most unwieldy complexes are formed.

So far nothing has been said concerning the nature of the atoms themselves; but assuming that they can be formed of groupings of circular vortices, it becomes of interest to see what combinations are stable, and therefore possible. It has been shown that the greatest number of columnar or cylindric vortices which can waltz round one another in stable equilibrium is six; but Mr. Hicks surmises that, the circular form being a little more stable, a combination of as many as seven *rings* may be able to group together, threading each other in regular succession, and forming a single atom of a definite kind, up to which there are six grades, constituting other and simpler kinds of atoms. To form a more complex atom than this, these seven rings must be treated as a single atom, which can begin to link itself with from one up to seven others; and then the grouping will begin again; so that the properties of the elements and their atomic weights will fall into octaves. Should this view be borne out by hydrodynamical calculation the meaning underlying Mendelejeff's law will have a good chance of displaying itself; or rather, it will have been completely displayed.

So busy was section A, that on Saturday, when many of the sections took a holiday, it split itself into two in order to get through its work; and even so, one of the sub-sections continued sitting till 3 P. M.

Towards the end of the day the report of the electrolysis committee was read. It was a short statement of the work that had been done by the members during the past year, and was followed by a few papers. The communication of Lord Rayleigh concerning the velocity of light in electrolytes should have formed part of this report, and would have done so had the secretary of the electrolysis committee (O. J. L.) looked after its interests as he ought.

Professor Fitzgerald and Mr. Trouton have continued their investigations into the accuracy with which electrolytes obey Ohm's law, and are now able to state that if there is any discrepancy for sulphate of copper it is less than three parts in a million. This is a very satisfactory result, the obtaining of which means a good deal of careful work as well as an ingenious method.

An account of Dr. Gladstone and Mr. Hibbert's experiments on the conduction of alloys and solid sulphides followed, wherein it was shown that the conductivity of fusible alloy was mainly and probably wholly non-electrolytic, while sulphides of the form M_2S were most of them electrolytically decomposed by a current.

Professor Armstrong and Dr. Arrhenius contributed some critical remarks on the general theory of electrolysis, which, however, in their absence, were taken as read, and will be printed with the report.

Mr. Shaw communicated a paper sent by Dr. Richarz, from Berlin, containing an account of some experiments on the polarization E. M. F. of a voltameter with very small electrodes, wherein he switched the voltameter cell quickly from a charging battery to a galvanometer by means of a Helmholtz pendulum, and thus obtained values of the polarization decidedly lower than had been previously obtained with point electrodes by Buff. Richarz seeks to explain the difference by neglected heat effects.

The time of Tuesday was so largely taken up with a discussion on lightning conductors that Dr. Fleming's two papers "On a Form of Standard Resistance Coil," and "On a Commutator for Charging and Discharging a Condenser at a Known Rate," had to be taken as read.

Mr. Glazebrook stated the results of his continued most careful investigation into the state of the old B. A. standards of resistance. Examining them with the most minute accuracy and plotting their results over a certain range of temperature, their curves all nearly intersect at a temperature where they are supposed to be correct. They do not, of course, exactly intersect at a point, but they agree very well; and, what is of most interest, they have preserved their relative values among themselves ever since they were first exactly compared by Dr. Fleming in 1875 (?). All except one, which has recently begun to show distinct signs of aberration, probably by reason of some slight defect in insulation. Since these coils are the world's material standard of resistance at the present time, it is most desirable to know that they are constant; and, inasmuch as they are made of different materials and have preserved their relative values, it is practically quite certain that their absolute values have remained unchanged.

The committee on electrical standards are undertaking experiments with a view to construct a reliable standard of electrostatic capacity, and are examining some air condensers constructed and measured some time ago by Dr. Muirhead.

Mr. Preece's paper on C. G. S. units is really a communication to the electrical standards committee, asking them to sanction the use of the term "joule" for the work done by a watt in a second, as proposed by the late Sir W. Siemens. The committee have acquiesced in the suggestion, and the Joule is, therefore, now 10,000,000 ergs, or a coulomb-volt. They have also, at Mr. Preece's instigation, sanctioned the name "therm" for the water-gramme-degree-centigrade unit of heat, the absolute unit of heat being either the erg or the joule, according to taste. The joule will make a unit of heat of very convenient size, because 4.2 such units will equal one therm. In other words, the absolute specific

heat of water will be henceforward 4.2, and the specific heat of other things in proper proportion.

Mr. Preece further proceeds to lament the unfortunate circumstance which has caused the ampere to be one-tenth of the C. G. S. unit of current instead of one unit. He is sanguine enough to hope even yet for a change in this matter; but the feeling of the committee was not with him, though they all felt the inconvenience of the present state of things.

Another matter which he has succeeded in inducing the committee to take up is a re-determination of the specific resistance of pure copper. It appears that copper is now supplied commercially by manufacturers which eclipses the standard as tested by Matthiessen, and which was known in his day as pure copper.

Sir William Thomson described a determination of the product μK for air, commonly called a determination of the velocity of electro-magnetic waves "v." A certain condenser had its capacity measured electro-magnetically at Glasgow with the use of one of Sir William's new standard current weighing instruments, and it was then measured electrostatically in London by Professors Ayrton and Perry. The resulting value of "v" comes out from the experiments, so far made distinctly too low, something like 293,000 kilometers per second, with a possible total error of 1¾ per cent.; as compared with the 299.5 thousand kilometers per second determined by Professor Rowland, with very perfect condenser, absolute electrometer and ballistic galvanometer. Most of the German determinations of "v" slightly exceed 300; most of the British determinations slightly fall below it. If the method now described is to give a reliable value, it will doubtless be repeated many times, and the somewhat large margin of error reduced.

In connection with absolute determinations of great accuracy, it is surprising how many difficulties come in, such as seldom have to be thought of in ordinary laboratory observations. Considering all the care that has been taken in the construction of standards of length, it is rather depressing to be told by Professor Rowland that the standard meter is an uncertain quantity, and that the various meter standards in use differ by so much as one-tenth of a millimeter, or a hundredth per cent. People accustomed to speak glibly about obtaining an accuracy of a tenth or a hundredth per cent. in their measurements little know what they are talking about. Probable errors of as much as one per cent. in an absolute measurement are much more frequent than is by many persons suspected.

Mr. Glazebrook has been most carefully and for a long time examining the specific resistance of mercury in glass tubes, a measurement which has revealed unexpected difficulties and distinct though minute discrepancies from previous determinations. There can be little doubt that Mr. Glazebrook's results are the most accurate yet obtained, and he states that the true ohm is equal to the resistance of a square millimeter column of mercury 106.29 centimeters long.

We are here getting down to the limit of accuracy with which the standard meter itself is known.

Sundry minor communications may be hastily glanced through. A method of utilizing an electric current for calorimetry, by Professor Stroud and Mr. Gee, really belongs to the subject of heat. Mr. W. N. Shaw exhibited an arrangement for measuring the average temperature of an extended body, consisting of wires imbedded in a long ribbon of india-rubber which could be wrapped about the body, and the resistance of the wire measured. The wire is made in two branches, each of a different metal, so that a differential galvanometer balance can only be exactly obtained at one particular temperature, and the compensation needed to correct any outstanding error is used to obtain the temperature. It is said to give it to about $\frac{1}{100}$th of a degree. Mr. J. Brown, of Belfast, exhibited some pretty and curious branching figures made by an electric spark on an ordinary photographic dry plate. Mr. Lant Carpenter stated some particulars concerning the E. M. F. and internal resistance of Gassner's jelly-filled battery cells, as measured by Mr. Rimington; and last, though not least, Sir William Thomson described some experiments made in his laboratory by Mr. Tanakadaté on the magnetization of soft iron bars of different lengths in a uniform field. This paper the writer regrets not having heard.

And now we have cleared the course for the lightning rod discussion, which excited a good deal of interest, and which really was a discussion, in which many prominent members of the section took part, and on which much more might have been said had there been time.

The discussion is being reported in this journal pretty nearly verbatim; but out of such a mass of matter it will be difficult for anyone to pick out the salient points of difference between the opposite camps, and it may be useful to bring them into more marked relief.

The opposite camps may be styled the Practical *vs.* the Theoretical. On the one side we find constructors of lightning rods, members of the lightning rod conference, meteorologists, and engineers; a miscellaneous body of great experience headed for the time being with efficiency and good humor by the president of Section G, who has necessarily in his official position an enormous number of lightning protectors under his supervision.

On the other side we find some laboratory experiments, and a theory of the alternating character of a discharge, combined with a mania for talking about self-induction or electro-magnetic inertia, and for poking this idea into a lot of places where it does not naturally seem to fit; excluding its influence, however, from other places where one would expect to find it, such as the interior of an iron rod.[1]

If views and statements so founded are to make headway against the experience of practical men, and to gradually introduce reform into existing procedure, it must be by reiterated statement and discussion, and after gradually acquired further experience under circumstances and conditions arranged to test the new views on a large scale. On the other hand, if the self-induction mania has no sound basis in fact, the surest way of destroying it is to bring it into the arena and expose it to conflict. Hence it is that the organizing committee of Section A arranged for the opposite camps to meet and skirmish at Bath.

The combat was not waged to the death, the lists being cleared before the combatants were half exhausted, so that it is quite possible they may meet again on some other arena. Meanwhile, the points at issue may be summarized thus: selecting those statements of Mr. Preece and his supporters which seem most generally accepted, or likely to be accepted, on that side; and numbering the opposing statements so as to correspond with them. No statement is here quoted or suggested which, to the writer, seems entirely absurd; because absurd statements may easily be made in debate without sufficient thought, and because such statements are not likely to be generally or weightily accepted, even if pressed by their propounder.

Statements made in the Practical Camp.	*Statements made in the Theoretical Camp.*
1. Properly constructed lightning rods never fail. When existing rods fail it is because there is something the matter with them—usually an insufficient earth.	1. Rods as at present constructed, though frequently successful, may and do sometimes fail, even though their earth is thoroughly good; the reason being that they offer to a flash a much greater obstruction—a much worse path—than is usually supposed; an obstruction to be reckoned in hundreds or thousands of ohms, even for a very thick copper rod.
2. Leyden jar discharges have nothing oscillatory or alternating about them, or at least the existence of such alternations is an unproved assumption.	2. When a Leyden jar is charged it corresponds to a bent spring, and its discharge corresponds to the release of the spring. Its discharge current alternates, therefore, in the same way and for much the same reason as a twitched reed or tuning fork vibrates. The vibrations decay in either case because of frictional heat production, and because of the emission of waves into the surrounding medium. A single spark of a Leyden jar, examined in an exceedingly fast revolving mirror, is visibly drawn out into a close succession of oppositely-directed discharges, although its whole duration is so excessively minute.
3. Even if Leyden jar discharges should turn out to be oscillatory, there is no reason why lightning flashes should be of the same character. Lightning flashes have an apparent duration, and transmit telegraph signals, deflect compass needles, and do other things which alternating currents could not do.	3. A lightning flash is a spark between cloud and earth, which are two oppositely electrified flat surfaces, and the flash corresponds therefore to the internal sparking between the two plates of a great air condenser. All the conditions which apply to a Leyden jar under these circumstances are liable to be true for lightning. Sometimes the resistance met with, either in the cloud itself or in the discharger, may be so great that the spark ceases to be oscillatory, and degenerates into a fizz or rapid leak; but there can be no guarantee that it shall always take this easily manageable form; and it is necessary in erecting protectors to be prepared for the worst and most dangerous form of sudden discharge. The apparent duration of a lightning flash is due to its frequently multiple character, and indicates successive discharges, not one long-drawn out one. Nothing that lightning has been found to do disproves its oscillatory character; because Leyden jar discharges, which are certainly oscillatory, can do precisely the same.
4. The one thing needful for an efficient lightning protector is conductivity, sufficient conducting power to convey the whole charge quickly and harmlessly down to the earth, with which the conductor must make elaborate contact.	4. Although some conductivity is necessary for a lightning conductor, its amount is of far less consequence than might be expected. The obstruction met with by an alternating or rapidly varying discharge depends much more on electro-magnetic inertia or self-induction than upon common resistance. So much obstruction is due to this inertia that a trifle more or less of frictional resistance in addition matters practically not at all. It is very desirable to have a good and deep earth in order to protect foundations and gas and water mains from damage, and in order to keep total impedance as low as possible.

1. Professor Lodge's original lectures "On the Protection of Buildings from Lightning," were reprinted in *The Electrician*, June 22 and 29, July 6 and 13, 1888.

5. No danger is to be feared from a lightning conductor if only it be well earthed and be sufficiently massive not to be melted by a discharge. All masses of metal should be connected to it, that they may be electrically drained to earth.

5. The obstruction offered by a lightning rod to a discharge being so great, and the current passing through it at the instant of a flash being enormous, a very high difference of potential exists between every point of the conductor and the earth, however well the two are connected; hence the neighborhood of a lightning conductor is always dangerous during a storm, and great circumspection must be exercised as to what metallic conductors are wittingly or unwittingly brought near or into contact with it. When a building is struck the oscillations and surgings all through its neighborhood are so violent that every piece of metal is liable to give off sparks, and gas may be lighted even in neighboring houses. If one end of a rain-water gutter is attached to a struck lightning conductor the other end is almost certain to spit off a long spark, unless it also is metallically connected. Electric charges splash about in a struck mass of metal, as does the sea during an earthquake or when a mountain top drops into it.[1] Even a small spark near combustible substances is to be dreaded.

6. The shape of the sectional area of a conductor is quite immaterial; its carrying power has nothing to do with extent of surface; nothing matters in the rod itself but sectional area or weight per foot run, and conductivity.

6. The electrical disturbance is conveyed to a conductor through the ether or space surrounding it, and so the more surface it exposes the better. Better than a single rod or tape is a number of separate lengths of wire, each thick enough not to be easily melted, and well separated so as not to interfere with each other by mutual induction.

The liability of rods to be melted by a flash can be easily over-estimated. A rod usually fails by reason of its inertia-like obstruction, and consequent inability to carry off the charge without spittings and side flashes; it very seldom fails by reason of being melted. In cases where a thin wire has got melted, the energy has been largely dissipated in the effort, and it has acted as an efficient protector; though, of course, for that time only. Large sectional area offers very little advantage over moderately small sectional area, such as No. 5 B. W. G.

7. Points, if sharp, should constitute so great a protection that violent flashes to them ought never to occur.

7. Points, if numerous enough, serve a very useful purpose in neutralizing the charge of a thunder-cloud hovering over them, and thus often prevent a flash; but there are occasions, easily imitated in the laboratory, when they are of no avail; for instance, when one upper cloud sparks into a lower one, which then suddenly overflows to earth. In the case of these sudden rushes, there is no time for a path to be prepared by induction, no time for points to exert any protective influence, and points then get struck by a violent flash just as if they were knobs. Discharges of this kind are the only ones likely to occur during a violent shower; because all leisurely effects would be neutralized by the rain-drops better than by an infinitude of points.

8. Lightning conductors, if frequently tested for continuity and low resistance by ordinary galvanic currents, are bound to carry off any charge likely to strike them, and are absolutely to be depended upon. The *easiest* path protects all other possible paths.

8. The path chosen by a galvanic current is no secure indication of the course which will be taken by a lightning flash. The course of a trickle down a hillside does not determine the path of an avalanche. Lightning will not select the easiest path alone; it can distribute itself among any number of possible paths, and can make paths for itself. Ordinary testing of conductors is therefore no guarantee of safety, and may be misleading. At the same time it is quite right to have some system of testing and of inspection, else rust and building alterations may render any protector useless.

9. A certain space contiguous to a lightning rod is completely protected by it, so that if the rod be raised high enough a building in this protected region is perfectly safe.

9. There is no space near a rod which can be definitely styled an area of protection, for it is possible to receive violent sparks or shocks from the conductor itself. Not to speak of the innumerable secondary discharges which, by reason of electro-kinetic momentum and of induction and of the curious recently discovered effect of the ultra-violet light of a spark, are liable to occur as secondary effects in the wake of the main flash.

Just one word on the subject of iron *vs.* copper. The writer last year thought and stated that, in so far as the substance of the conductor was magnetized by a discharge, iron would obstruct a lightning flash or any other rapidly varying current enormously more than copper does. But the fact is, that the substance of a conductor is, by sufficiently rapidly alternating currents, not magnetized at all. The current is tubular, keeps wholly to the outer surface, and magnetizes nothing inside. Hence the magnetizability of the substance of the conductor is of no moment at all; and iron, therefore, will do every bit as well as copper. Mr. Preece's experience with half a million iron wire telegraph post protectors leads him to uphold iron as entirely satisfactory. So, on this one point, as well as on the necessity existing for a good earth, a portion of the practical and of the theoretical camps have been able to agree.

Immediately after the discussion Dr. Janssen exhibited some preliminary attempts at photographs of lightning taken with a double-nozzled camera, having two sensitive plates, one fixed, the other revolving 30 times a second.[2] The same flash was depicted on both plates, but on the moving plate it was separated into two or three distinct streaks, showing its multiple character. Each constituent, however, was as clear and distinct on the rotating as on the fixed plate, and had, in fact, exactly the same shape and appearance, so that one could be superposed on the other exactly; thus proving its instantaneous character. The rate of spin was naturally nothing like sufficient to exhibit the alternating character of each constituent.

It is to be hoped that many more photographs of lightning will be taken on this plan, because there are evidently many kinds of composite flashes, and it is an excellent way of analyzing them and correcting the impressions, often erroneous, formed by the eye.

On the whole, the Bath meeting, though not largely attended by the temporary class of members and associates, may be considered, so far as Section A is concerned, as one of the most interesting and important that have ever been held—thanks largely to the excellent arrangements made by the secretaries; and the discoveries of Hertz, referred to by the president in his address, mark a distinct epoch in our acquaintance with electro-magnetic phenomena.

ABSTRACTS AND EXTRACTS.

PRACTICAL EXPERIENCE IN THE USE OF ACCUMULATORS.

BY LEONARD PAGET.

MUCH—indeed a great deal too much—has been said for and against accumulators. Those interested in commercial sales have extolled these valuable auxiliaries beyond every reasonable limit; disappointed purchasers have decried all accumulator systems. Those who have not yet tried electrical storage have before them only two reliable ways of making judgment—by accepting unbiased and competent authority, or by actual trial. In this view there are here given abstracts of the statements of Professor Köhlrausch,[1] whose name is accepted in Europe as a synonym for accuracy and reliability in electrical work.

The principal advantages of accumulators are the following: They are always ready for use; we know exactly what can be obtained from a charged battery; the efficiency of an accumulator, compared to that of a primary battery is high and especially certain; the internal resistance is extremely low.

The inconveniences may be enumerated as: The accumulators have to be charged before they can be used; they are too heavy to be easily transportable; it is necessary to recharge the accumulators immediately after discharge, to avoid deterioration of the plates; during the last of the period of charging, the bubbles of gas that escape carry with them sulphuric acid which attack metallic bodies in the neighborhood, and also provoke coughing.

The inconveniences of the old systems of accumulators, as for example, the fall of plugs from the lead grids, the buckling of positive plates, have been eliminated. And it appears as if we should arrive in time at the construction of accumulators of which we can guarantee a duration of several years.

Phenomena during charge and discharge with currents of normal quantity.—The absolute value of the electromotive force of an accumulator depends not so much upon its form as upon the quantity of current; it is proportionately lower during charging and higher during discharge as the current is greater.

The values of the E. M. F. vary a little from one cell to another; however, the following mean values apply to the majority of cases. The mean potential difference reaches 2.15 to 2.16 volts during charge, and 1.86 to 1.9 volt during discharge, supposing a normal quantity of current. The ratio of these two values is about 0.87.

There is recovered generally in the discharge 90 to 93 per cent. of the quantity of electricity stored (in ampere hours) during the charge, with the restriction that the interval between charge and discharge does not exceed one to two days. The efficiency of a good accumulator is then $0.87 \times 0.915 = 80$ per cent.

The normal quantity of current is determined by the dimensions of the free surfaces of the positive electrodes. The density

1. Annalen-Wiedemann, vol. 34, p. 583.

of the current per square decimeter varies, according to the form of accumulator, between 0.5 and 0.7 ampere.

Measurement of internal resistance.—This measurement which offers certain difficulties by reason of the small value of the resistance and the high electromotive force, may be most easily made during charge and discharge. Let e be the electromotive force, p, the difference of potential at the terminals, i, the current, r, the internal resistance; there obtains

during the charge............ $p = e + i r$
" " discharge.......... $e = p + i r$.

The E. M. F. of the accumulator on open circuit is measured immediately before the charge and before the discharge; and the difference of potential at the terminals, p, is subsequently measured just after closing the charging or discharging circuits.

By substituting the values obtained in the above equations, there are given the corresponding values for the internal resistance. The resistance of the element discharged is a little greater than that of the element charged, because of the sulphate of lead formed and because of the lower conductivity of the acid solution.

Phenomena occurring during irregular charging and discharging.—The capacity of the accumulator increases proportionately as the quantity of the current in charge and discharge decreases. With irregular working, the value of a discharge depends not only on the preceding charge but also on previous charges and discharges.

Reciprocally, a prolonged discharge with a small current weakens the subsequent discharges effected with a normal current. The causes of these anomalies lie probably in a residual formation still insufficiently explained.

The efficiency of the accumulator may, in particular cases, fall as low as 60 to 70 per cent. and even surpass 100 per cent. It is necessary to avoid as far as possible all discharges with a current of small quantity.

It is necessary never to leave accumulators discharged, because there is then produced sulphate of lead at both electrodes, which increases the resistance of the cell. If accumulators remain long out of use, it is necessary to charge them from time to time until gas is given off; it is also recommended to charge and discharge them from time to time normally.

If there is reason to suppose that a cell of the battery does not work in a normal manner, the accumulators should be examined first in groups, and then one by one of the defective group by rapidly measuring the electrical pressure.

Installation of new cells.—It has been the practice hitherto for the maker to deliver the plates and vases separately. As soon as they arrive, the plates should be washed with a small mop slightly damped; if the plates are separated, they must be reconnected and soldered to the connecting bars. The solution of acid is then to be prepared by employing rain water and the commercial sulphuric acid known as pure acid. The vase is to be so filled as to moisten the plates only as the liquid rises in the vase. A normal charge is then to be given and continued to the end without interruption. If the full capacity is not obtained in the first charges, the battery is to be surcharged until the desired capacity in ampere-hours is attained.

Professor Köhlrausch cites the case of accumulators that should have given 44 ampere-hours with a discharge of 6 amperes, and that actually gave only 30 ampere-hours; by surcharging them for 12 hours, they subsequently gave permanently a capacity of 47 ampere-hours.

It is advisable to cover the accumulators with a plate of glass to avoid the diminution of the solution by evaporation and the carrying over of the liquid by development of gas (spraying). The proper quantity of liquid may be renewed once or twice with water, for its density may vary without inconvenience between wide limits. It is requisite, however, from time to time to bring the liquid up to its normal density; to this, the battery is to be divided into groups of 5 to 10 cells, and the average density of the liquid of each group determined; thus the missing quantity can be prepared and such density given to it as that when mixed with the liquid remaining in the accumulators will give a normal density. Each (discharged) accumulator is then, by means of a pipette, refilled with liquid, and afterwards charged.

It is necessary never to completely empty the accumulators, because the negative electrodes heat rapidly on contact with air in consequence of the energetic oxidation of the finely divided lead. If the negative plates are to be removed, the most simple plan is to place them in an atmosphere of illuminating gas.

Charging accumulators.—The best machines for charging accumulators are shunt-dynamos. It is very convenient to intercalate a rheostat in the circuit, The following example illustrates the advantages. Suppose it is wished to charge a battery of 50 accumulators of 0.005 ohm resistance with a current of 20 amperes. The total resistance of the accumulators being 0.25 ohm, it is requisite that the tension of the machine should exceed that of the battery by 5 volts; now the tension of the battery rises gradually from 105 to 115 volts, and it is necessary that the machine follows in the same ascending ratio from 110 to 120 volts, which may be caused to occur by varying the velocity of the machine or the quantity of the shunt current in the field magnets. It is much better practically to insert a resistance of 0.5 ohm in the circuit and to diminish the resistance little by little, so as to keep the current constant at 20 amperes. This auxiliary resistance diminishes, besides the variation of current produced by variation in the speed of the machine.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Board of Electrical Control.—Dr. Wheeler's Lecture at the Young Men's Christian Association.—Resignation of Mr. C. O. Mailloux, from the Julien Co.—The Complaint against the U. S. Illuminating Co.—The Brooklyn Bridge Lights.—Electric Lighting for the "Puritan."—Permit Granted Edison Company by Brooklyn Aldermen.—Re-opening of the Telegraph School of Manhattan Elevated Road.—Annual Receipts of Elevated Roads.—Mayor Hewitt's Answer to Ex-Gov. Cornell's Letter.—An Electrical Storm.

THERE are evidences of an effort on the part of the Board of Electrical Control to systematize their details and methods for more effective work. As an electrician recently remarked: "They are just beginning to find out what they don't know."

Mr. C. O. Mailloux, who has been the consulting electrical engineer of the Julien Electric Co. since its organization, has resigned his position.

Dr. Schuyler S. Wheeler's lecture upon "Electricity and its Modern Applications" at the Young Men's Christian Association Rooms, on October 5th, was so well attended that several hundred persons were unable to gain admission. The lecture was illustrated by a number of experiments showing the effects of induction, the advantages of electric motors for power purposes, the operation of transformers, etc. The East River Electric Light Co. furnished circuits for arc and incandescent lamps. Dr. Wheeler was assisted by Mr. Francis B. Crocker. In the course of his remarks, Mr. Crocker spoke earnestly of the opportunities afforded young men in the electrical field.

The complaint of President Hess, of the Board of Electrical Control, against Mr. Eugene T. Lynch, president of the United States Illuminating Co., charging that company with maintaining a nuisance, by keeping its wires above ground, came up for examination at the Jefferson Market Police Court, on October 2d, but on account of the absence of the attorneys for the prosecution, Justice Duffy adjourned the examination for one month.

There has been some objection raised by navigators to the electric lights upon the Brooklyn Bridge, and a demand made that they be screened. The lighthouse board claim they are a violation of their regulations. District-attorney Walker, however, in a communication to the attorney-general states that no rule referring especially to the Brooklyn Bridge, has been adopted, and there is no existing rule covering the matter, and if there was it is not clear that there is any provision which makes it an offence to maintain lights that are a hindrance to navigation. He therefore recommends that Congress pass an act prescribing a punishment for disobedience to the orders of the lighthouse board, and that the board make some definite order on the subject.

President Howell, of the bridge trustees, believes there is no necessity for screening the lights. He says that the bridge has been so lighted for five years, and during that time no pilot has ever made complaint; the only protests received were from the same men who objected to the construction of the bridge.

The new Sound steamer "Puritan" is to be lighted by 1,600 Edison lamps.

The Brooklyn aldermen have passed an ordinance giving the Edison company the right to do business in that city. The newspapers who are opposed to Governor Hill's re-election allege that it was clearly a campaign trick—Governor Hill having vetoed a legislative act giving that company the same privileges in return, it is said, for political support.

The management of the elevated railroads have decided to reopen the Chatham square school of telegraphy. They propose giving their gatemen instruction so that in case of strikes or other trouble, operators can be provided. The present operators object to this, alleging that it is but a scheme to reduce their wages.

The mayor has requested the elevated roads to put on more trains, which they have agreed to do. One is fortunate at present if he secures a seat at any time during the day. The yearly receipts of the Manhattan Railway Co., as reported to the state comptroller, are $8,519,019, an increase of $629,944 over the past year.

There is a decrease of receipts reported on all the surface roads with the exception of the Third avenue, which shows a slight increase.

Col. J. A. Corby, who is largely identified in telephone, electric light and railway interests along the Missouri river, has been in the city for several days.

In declining to enter into an elaborate controversy with ex-Governor Cornell, over the question of electrical conduits, Mayor Hewitt writes:—

"I can only say that every man has his limitations. I am conscious of my own lack of ability to take in the whole compass of human enterprise, and I am compelled to confine myself to the consideration of such matters as are brought before me day by day, and to decide such questions as I am compelled to answer, according to the best of my judgment. This duty I have performed, and shall continue to perform to the end of my term; but I have no time to discuss with you or any one else, matters which I do not understand and have not time to study."

On the morning of the 17th, this city was treated to a magnificent meteorological display, the like of which it is said has never before been seen in this city. All persons who looked out of window about half-past six, saw a memorable spectacle. A lurid yellow, flaming sky, suggestive of a general conflagration—a sort of portent that would have terrified the mass of men some hundred or two years ago. Although the storm was of short duration, serious trouble was experienced upon all the telegraph wires, the atmospheric disturbance being almost entirely electrical. Lightning struck in front of the Washington Building, No. 1 Broadway, throwing off the cover of a subway man-hole and tearing up the pavement for some distance around. Investigation revealed no damage to the subway.

NEW YORK, October 29, 1888.

PHILADELPHIA.

Underground Work Going Forward; a Comprehensive Plan to be Carried Out.—Harrison Bros. & Co.'s Suit against the Telegraph Companies.—The Leber Regulating Incandescent Lamp.—The Electric Light Question Before Councils.—The Keystone Company's Suit.—The Bell Telephone Co., of Philadelphia, will Erect a New Building.

THE much talked of, but long delayed, movement for the burial of telegraph and telephone wires in this city has begun in earnest, and the Western Union Telegraph and Bell Telephone companies propose to spend $250,000 to put all their wires underground between the two rivers and Vine and Fourth streets. The work has already begun, and the wires east of Fifteenth street will be underground before many months shall have passed.

Those west of Fifteenth will go under the surface of the streets after the others shall have been buried. The contract for the building of the conduits has been awarded to Charles A. Porter. Already a conduit of brick has been laid on the south side of Market street from the Delaware River to Fourth street. It is 4 feet in width and 8 feet high. Within this conduit has been placed 49 iron pipes, each 3 inches in diameter. Each pipe will hold 100 wires, so that the capacity of the conduit will be 4,900 wires. The conduit will extend out Market to Thirteenth, up Thirteenth to Arch, out Arch to Fifteenth, and down Fifteenth to Market, and thence to the Schuylkill River. The conduit on Market street will be known as the trunk line, and at every other cross street, branch conduits will be laid to carry the wires north and south.

The plan that will be followed in making connections with buildings has been approved by city councils and the board of highway supervisors. The wires will be carried underground to the centre of each block, where a tall pole, 75 or 100 feet in height, will be erected, and from this point the wires will be run into the rear parts of the buildings. For instance, the block bounded by Second, Third, Chestnut and Market streets will be fed from a pole erected in Elbow lane. The block bounded by Second, Third, Chestnut and Dock streets will receive its wires from a pole erected in Carter's alley, midway between Second and Third streets. By this plan all the telegraph and telephone wires on the streets will be buried out of sight, and the objectionable poles removed as well.

The location of the trunk line on Market street will compel the removal of the Bell Telephone Co.'s exchange from Fourth and Chestnut streets to a place on Market street, not far from its present location. Mr. W. B. Gill, general superintendent of the Western Union Telegraph Co. for this district, said yesterday that the change would be a great improvement, and that it would be pushed to completion as rapidly as circumstances will permit. He said the business centre of the city will, in a comparatively short time, be completely free from overhead wires.

"This is the largest and most complete system that has ever been undertaken in any city in the country," said Mr. Gill. "While in Chicago recently I was driven over that city in every direction, and I can say there are more poles and wires in that city than in the same amount of territory in Philadelphia. While it is true that in a limited portion of that city there are no poles, wires are strung overhead from house to house. In no city of the United States has there been so earnest an effort made for placing wires underground as in Philadelphia. The Edison Electric Light Co. is placing miles of underground tubes and wires in the Penn company's trenches in addition to its own, and the city itself, through its electrical bureau, has an underground system that will compare favorably with that of any other city. While the electrical companies have done much toward the development of the underground systems, too much praise cannot be bestowed upon Mayor Fitler for the time and labor he has given to the placing of wires underground. It is a well-known fact that several of the underground systems adopted in Chicago have proved failures, and it is hoped and believed that the improved conduits now being laid in this city will be successful.

The long-pending litigation, in which Harrison Bros. & Co. are the complainants and the Franklin, the Atlantic and Pacific and the Western Union Telegraph companies are the defendants, was recently under argument before Justice Bradley in the U. S. Circuit Court.

The contract out of which the suit arose was made twenty-one years ago. It appeared that when the Insulated Lines Telegraph Co. was about to be merged into the Franklin company, in 1867, Harrison Bros. & Co. made an agreement with the Franklin company to erect at its own expense a wire between New York and Philadelphia. The firm was given the priority of the use of this wire for the transmission of despatches for themselves and four other parties who were in the position of the firm's licensees. This contract was to remain in existence for ten years and then the wire was to be the property of the Franklin company, and the firm was to pay $600 per annum for its use. The Franklin company eventually became the property of the Western Union, which endeavored to terminate the arrangement, and the matter finally drifted into a legal controversy.

In 1882 the firm brought equity proceedings for the purpose of restraining the telegraph companies from depriving them of the use of their private wire. Much testimony was taken, and this now forms the subject-matter of the spirited argument of counsel. The construction of the wire in the first place, it is claimed, cost the firm $10,000, and the $600 rental has been promptly paid since 1877. The privilege is a very valuable one at present. The question before the Court is whether the contract still holds good or whether it must be considered terminated. The argument will be resumed this morning.

The working of the Leber regulating incandescent light were shown a short time since in the *Ledger* job office to a number of gentlemen interested in electric lighting. The invention is one by which the brilliancy of the light may be increased or decreased by the turning of a key, the same as an ordinary gas light attachment. The light shown was regulated to show any degree of brilliancy from one sixteenth of a candle power to one hundred candle-power. The exhibition was a highly successful one, and the new light will be taken in hand by a number of Philadelphia capitalists.

A resolution was recently adopted in councils providing for the appointment of a special joint committee to investigate the electric light question. The city, the resolution stated, pays to electric light companies $129,000 a year for 755 arc lights. This was claimed to be excessive, as the city, with a plant of its own costing $300,000, could supply light to 2500 or 3000 lamps at an annual expense of $90,000. The companies were also charged with furnishing only 1200 candle-power to many of the lamps, while their contracts call for 2000 candle-power. In view of these statements the committee was instructed "to investigate and report, with such recommendations for legislation as may be decided necessary to remedy the evils presented and further the best interests of the city." Messrs. Jones, Graham, Freeman, Thornton and Moffett were appointed as select council's half of the committee. In speaking of the resolution, Mr. Graham said that the electrical committee had considered the matter and had found that the plant would cost $400,000, and the annual expense would be more than $90,000. "Still we don't get the light we are paying for," he admitted.

Court of Common Pleas No. 1 has decided not to pass on the question of law involved in the suit of the Keystone Light and Power Co. until action shall have been taken by the electrical committee of councils.

The company wants the city restrained from interfering with its underground work. Judge Allison said that the plaintiffs should try and use some means to obtain a decision from the electrical commission, but the Court would not allow the purposes of justice to be defeated by inaction, and would take a long delay to be a refusal to grant the privileges asked for, and would then adjudicate the points involved.

The Bell Telephone Co. has purchased the buildings Nos. 406 and 408 Market street, and will erect thereon a new structure, four stories high, which will be used as its exchange. The removal from Fourth and Chestnut streets is made necessary by the burial of the "trunk line" of telephone wires along Market street. The company cannot take possession of the property until January 1st, 1889.

PHILADELPHIA, October 17, 1888.

.... I SET very little value on the speculations of even our admittedly greatest scientific men, unless they be supported by experiment.—*S. Alfred Varley.*

.... I DO not think that in actual practice there is an average waste of 10 per cent. in the use of converters when they are properly designed.—*Professor George Forbes.*

BOSTON.

The New England Electrical Exchange.—An Inspector of Electric Wires Proposed.—Meeting of the New England Electrical Exchange.—Interference with the Work of Firemen by Overhead Wires.—A Cross Causes Danger to the Wooden Dome of the Central Fire-Alarm Station.—Controversy at Newton between Gas and Electric Interests.—Monthly Statement of the American Bell Telephone Co.—Testing the Long-Distance Telephone Lines.

THE New England Electrical Exchange held its quarterly meeting in the rooms of the Boston Electrical Club, No. 66 Boylston street on the afternoon of the 8th inst. President P. H. Alexander occupied the chair, and delivered an address reviewing the work of the exchange, pointing out its increasing usefulness. A letter from Professor W. A. Anthony, of the Mather Electrical Manufacturing Co., of Manchester, Conn., a member of the examining board, suggesting alterations in the plan of licensing, was read, and the alterations adopted. As the legality of the licenses issued by the exchange had in some cases been questioned, it was voted to obtain a charter of incorporation, and a committee of three was appointed for that purpose.

Saturday evening, the 6th, a fire in the six-story warehouse numbered 411 and 413 Atlantic avenue and 74 and 76 Purchase street, necessitated three alarms and caused a loss of fully $50,000, one-fifth of which is on the building. There is no doubt that the loss would not have been nearly so great had not the mass of electric light wires in front of the building on Atlantic avenue interfered so seriously with the work of the firemen. These wires made it impossible for the men to stand on the ladders without receiving shocks from the electric fluid. One fireman came in contact with an electric light wire while he was standing on a ladder, and received a severe shock, which necessitated his removal to the City Hospital. The injuries of other firemen from the same cause was slight. At last the electric light companies shut off the currents of electricity, and then the firemen went to work with a will and soon had the fire under control.

At the meeting of the board of aldermen on the 8th inst., a special committee of three members of the board of aldermen was appointed to inquire into and report what action can be taken by the board of aldermen to protect the lives of firemen and property from the danger arising from overhead electric wires.

The regular session of the aldermen was held Oct. 15, and the following communication received from the mayor:—

City of Boston,
Executive Department,
Oct. 15, 1888.

To the Honorable, the City Council:

GENTLEMEN:—

I submit herewith a communication from the Boston Board of Fire Underwriters in relation to overhead wires. I have long felt that an inspector of overhead wires was a necessity and will be a necessity until some practical system of placing all wires underground is ascertained. I, therefore, heartily indorse such an appointment, and believe that such an official should be attached to the fire department. This department relies on overhead wires for the efficient performance of their work, and these wires should be protected. The firemen should also be protected in the performance of their duties from the danger of overhead wires. The irregular way in which most wires are put up should be remedied, all wires not used should be removed, and all overhead wires should be under the charge and direction of an inspector, whose duty it would be to see that they were so placed as not to endanger life or property. I am satisfied this can be done, and hope that the city council will give it favorable consideration.

Respectfully submitted, HUGH O'BRIEN, Mayor.

The communication of the Boston Board of Underwriters is as follows:—

Boston Board of Underwriters,
No. 70 Kilby street,
Boston, Oct. 13, 1888.

To His Honor the Mayor, and the Honorable City Council of the City of Boston:

GENTLEMEN:—

The undersigned, representing the Boston Board of Fire Underwriters, respectfully petition your honorable body to take into consideration the advisability of creating the office of inspector of electric wires. While at the present time the board which the undersigned represent undertake an inspection and supervision of electric light wires for the purpose of preventing loss to life and property by unsafe methods of running these wires, it is beyond their power to in any way regulate the running of telegraph, telephone and other wires through the streets or over the tops of buildings. In the absence of all inspection and regulation these wires are run in such a manner as best suits those who put them up. They are frequently brought into dangerous proximity with electric light wires, and at other times are run in such a manner as to greatly interfere with the work of firemen endeavoring to extinguish a fire. In the opinion of your petitioners great gain would result to the citizens of Boston if the running of electric wires of all kinds could be placed under strict official supervision, compelling the various electric companies to give notice in advance of their intention of running wires, and making it necessary that they should obtain the approval of the official inspector of the route selected before they could proceed with their work. In this way many of the dangers which are now from time to time encountered might be obviated.

We would, furthermore, suggest that a license fee might be charged the various electric companies which would be amply sufficient to defray the cost of a thorough inspection.

Trusting that your honorable body will take this public matter into favorable consideration, your petitioners subscribe themselves,

J. EDWARD HOLLIS, President,
OSBORNE HOWES, JR., Secretary,
Boston Board of Fire Underwriters.

The matter was referred to the committee on fire department.

The board of aldermen on the 21st inst. passed over the mayor's veto by a vote of eight to four the order granting Henry E. Cobb, Royal M. Pulsifer, Henry E. Chapman, and their assigns, leave to open up the city streets for the purpose of laying conduits for electric wires. This is stated to be virtually granting a monopoly of the underground conduit system of Boston.

On the night of the 1st inst. a cross with a heavily charged wire caused the burning out of the repeater in the dome of the City Hall building, and there was imminent danger to the large wooden dome. It is evident that a wooden structure is not adapted for the needs of the central fire alarm station, and the subject of changing the same into a substantial stone tower is being agitated.

The controversy between the Newton and Watertown Gas Co. and the Newton Electric Light and Power Co., was the subject of a hearing before the gas commissioners on the 11th inst. The gas company had the contract for lighting the City of Newton, and furnished 800 gas and 700 naphtha lamps. The contract expired last spring, and has been renewed for short periods twice since, pending legislative action on the right of the company to employ electricity. The electric company in the meantime has put in 70 arc lights, and offers to supplant gas and oil with 1,500 incandescent burners at less cost. The city continues both systems, pending the decision of the gas commissioners.

The statement of the out-put of telephones by the American Bell company for the month ended Sept. 20, is as follows:—

September—	1888.	1887.	Increase.
Gross output	3,920	4,110	*190
Instruments returned	2,156	2,152	4
Net output	1,764	1,958	*194
Dec. 21 to Sept. 20			
Gross output	41,660	40,651	1,009
Instruments returned	16,802	19,815	*3,013
Net output	24,858	20,836	4,022

*Decrease.

On the 15th inst. the long-distance telephone lines already constructed were tested from the executive offices of the American Bell Telephone Co. Conversation was carried on with Buffalo, and intermediate points. The results obtained were satisfactory, although it was stated that a few incidental faults remained to be remedied.

BOSTON, October 16, 1888.

CHICAGO.

Telephone Regulation Still Occupying City Councils.—Oscar G. Clark, an Electric Light Employe, Killed while Testing Lamps; the Coroner's Investigation.—Chicago Electric Club Notes.—Electric Railway Notes.—Lighting of the Columbia Theatre, Chicago.—New Incorporations and Corporation Notes.

THE telephone question is a source of endless trouble in the city council. The aldermen are continually fighting over it, and when they let the matter slide for a short time the papers pitch into them and cry boodle. The two ordinances introduced some months ago for the regulation of the business of the telephone company came up for consideration as special orders at the council meeting, October 8th. The first ordinance provided that the rental of instruments should be $95 the first year, and $85 each succeeding year, or $75 on three years' contracts; the other measures provided that no limit should be put on charges, but that the company should pay 2½ per cent. of its gross receipts into the city treasury. The former ordinance was recommended by the committee on licenses; the latter was a minority report of the same committee. The proposed measures were discussed, and amid some excitement the minority report was substituted for the majority report. Confusion began to reign and the aldermen adjourned without taking action.

The Chicago *Tribune*, in commenting on the action made a direct charge of bribery against the aldermen who voted to substitute the minority for the majority report. It asserted that the 2½ per cent. tax would bring into the city treasury $19,000. While by the readjusted schedule proposed by the majority report subscribers would be saved $275,000. The matter came up again at the meeting of October 15th. There was a radical change of sentiment. The aldermen after considerable discussion passed the ordinance, which provides that the rental shall not be more than $95 the first year, and $85 for each succeeding year, or $75 on three years' contracts. The measures also contained provisions requiring the company to furnish the central offices of city departments instruments without charge, to furnish instruments for the police and fire departments at $5 per year, and to bury a part of the circuits.

A great deal of pressure had been brought to bear on the aldermen to induce them to take this action. The druggists' association had adopted resolutions urging the council to reduce rates.

When the matter was under consideration Mayor Roche intimated his belief that the ordinance was illegal. Subsequently he said: "It is the opinion of the law department that the ordinance is invalid. I will not sign it. It is now simply a question whether the company will accept it. It scarcely seems probable that they

will do so, inasmuch as it compels them to charge less by $50 a year on three years' contracts than they are now obtaining. It has 30 days in which to accept the ordinance."

The officers of the telephone company were reticent on the question, president Phillips said he would not make any statement until he learned what action the mayor intended to take. He thought the mayor might suggest amendments which would make the ordinance more satisfactory. The city press still harps on the question. The *Tribune*, for example, urges the company to accept the ordinance and expresses the belief that the company by a refusal will make manifest an intention to defeat the will of the people by corrupt means. The *Daily News* is dissatisfied because the council did not reduce the rental to $50 per year. It is understood that Mayor Roche is in favor of taking such action as will bring the telephone question before the Supreme Court in a test case in order that the rights of the city on the one hand and of the company on the other may be speedily determined.

Oscar G. Clark, an employé of the Thomson-Houston company, was killed by an electric shock in the repair room of the company, October 3d. Clark was testing lamps at the time. The lamps were on a 50-light dynamo. The load varied from 44 to 46 lamps. The switchboard is located in the ceiling. Clark found that one lamp did not work satisfactorily. He had his left hand on a binding post of a lamp, and in his right hand he had a short stick with which to throw the switch. He could not reach the switch with the stick, so without removing his left hand from the binding post he jumped slightly. As he did so his right arm struck against the lamp lifting it slightly from contact with the hanging wire. At the same time his arm came in contact with the wire, thus short-circuiting the lamp. He received the full current. He groaned, staggered backward and fell upon the floor. The employés rushed to his assistance and endeavored to revive him. Meanwhile two physicians were summoned. They labored for two hours to resuscitate, him but without success. Beyond gasping twice the unfortunate man gave no sign of life. Clark was a bright ambitious young man with a decided tendency to make experiments on his own account.

The inquest was held October 5th. Two employés and George Cutter, the electrical engineer in charge of the department, were sworn. It was proved conclusively that the deceased had been instructed times without number, not to do the very thing which had caused his death. Mr. Cutter said an hour before the accident he had urged upon Clark the necessity of being extremely cautious in testing the lamps. He had also instructed the deceased not to adjust the lamps but to report simply whether they were working satisfactorily.

Professor Barrett asked whether the accident might not have been caused by a ground. Mr. Cutter was positive that it could not have occurred in such a way. The circuit was a short one, used only for testing purposes. It had been examined before and after the accident, and the resistance was found to be over 1,100,000 ohms. Mr. Barrett asked if Mr. Cutter had a certificate from the city inspector, permitting him to operate the plant. He replied in the negative. The plant, he said, was not complete in the first place, and in the second place he had been informed by the inspector that the ordinance relating to inspection was not enforced in testing rooms of electric light companies. Mr. Barrett was not satisfied, and insisted that the coroner submit to the jury a copy of the city regulations relating to operating electric light plants. The attorney of the Thomson-Houston company objected, but the coroner complied with the request. The jury brought in this verdict:—

"We, the jury, find that Oscar G. Clark came to his death from an electric shock while opening a switch in the Thomson-Houston company's works; also, that we, the jury, believe that the company is greatly to blame in not complying with the law."

Mr. Cutter said subsequently "The work in the shop is not of a temporary character. The circuits are all well put up. I should be glad to have any electrician look through the place and see the precautions against accident which I have taken. I had absolute cut-outs and had crossed my connections so that if a person touched two lamps he could not receive more than two-lamp tension. I had practically reduced the danger of fatal shock to a break in the circuit or an escape to ground."

A gentleman commenting on the fatality said, "The tendency of the bright young fellows in the business is to try experiments and to become careless. They are cured by receiving one good shock. I have known several young men thoroughly cured of all tendency in this direction by receiving a 500 volt shock."

The death of Clark was the fourth caused by the electric current in Chicago.

It seems to be the unanimous feeling in the Chicago Electric Club that more pretentious quarters should be secured. Most of the members incline toward a club house. The first fall meeting was held October 1. President S. A. Barton was in the chair for the first time. He made no formal address, but in three or four little speeches indicated his desire to see the club in better quarters. It was supposed that the matter would be settled October 15, but the meeting announced for that date was postponed by the board of managers. It is asserted on the one hand that the club cannot become a large and prosperous organization unless it secures a club house of its own. In order to obtain quarters of this kind it would be necessary to remove from a central location. Here another argument is presented. It is said if the club is located at a distance from the heart of the city the members would not visit it frequently; in other words, that the club would fail to accomplish the very objects for which it was formed—to promote a fraternal feeling among those interested in electrical matters and to secure the discussion of live topics pertaining to electrical science. The decision of this question will have an important bearing on the future of the club.

Theo. P. Bailey, manager of the railway department of the Chicago office of the Thomson-Houston company, has secured the contract for constructing the electric road at Alliance, O. The company has also secured the contract for installing an electric road for the Topeka (Kan.) Rapid Transit Co. The road will be 14 miles in length, and the cost of the installation will be considerably over $200,000.

The Columbia Theatre, Chicago, is now lighted throughout by electric lights. Nine hundred incandescent lamps and 20 arc lights are used. Many new features have been added of a kind to adapt the new system particularly well for effective stage work. C. C. Haskins, city inspector of electric lights, would not permit the location of an arc lamp in the dome unless the greatest precautions were taken to prevent sparks from the carbons causing a fire. The space above the lamp and the sides was lined with asbestos, and a mercurial thermostat located there.

The capital stock of the Central Electric Co., of Chicago, has been increased from $10,000 to $50,000.

The Dieckmann Electrical Co., of Chicago, has been incorporated with $10,000 capital stock. The incorporators are G. F. Dieckmann, Christian Wall, and David Quigg.

The Cutting Electric Alarm Co., of East St. Louis, Ill., has been organized. The capital stock is $8,000. The incorporators are W. H. Cutting, B. C. Graham, and B. Gratz.

The Alton (Ill.) Gas and Electric Light Co., has been incorporated with a capital stock of $60,000. The incorporators are Alvah E. Campbell, John Watt, and Levi Davis, Jr.

The Penrock Battery and Electric Light Co. is giving daily exhibitions of incandescent lighting by primary batteries. The company proposes to enter the field for installing isolated plants.

The Fort Wayne Jenney Co. will install the Slattery alternating street system in Galena, Ill. A converter will be provided for each street lamp.

The Thomson-Houston company, of Chicago, has been awarded a contract for 135 arc lights by the Dallas (Tex.) Electric Light, Power and Manufacturing Co.

CHICAGO, October 20, 1888.

MONTREAL.

Canadian Electric Light Notes.—A Painful Accident to Mr. Sise.—Visitors from the States.—The Federal Telephone Co.—Lectures by Mr. W. R. Kimball.

EVERYTHING electrical, as if in sympathy with the activity in the states, is on the boom in Canada. Especially so is electric lighting. More interest is now manifest here in lighting than ever before.

The Royal Electric Co. report as recent installations a 250 light plant at Granby. Six hundred lights are to be installed in the new Canadian Pacific station, with 12 arcs. The dynamo room is to be removed from the main building, when the special station house shall be completed. Thirty arcs and 700 incandescent lights are being installed in Joiliet by the town. Thirty arcs and 500 incandescents are being installed at St. Johns, P. Q.

They also report 30 arcs sold to the Toronto Electric Light Co., and an increase of 50 lights in the Orangeville plant.

The Edison company also make a good report. They have sold to the Royal City Planing Mills, Van Couver, a plant; and an increase of 50 50-c. p. lamps to the Van Couver Illuminating Co. Valleyfield, has made an increase to 300 lights. The Maritime Pulp Works, Chatham, N. B., have put in 375 lights. The James Crassen Car Works, Coburg, Ont., have placed 300 lights; R. Gardener & Sons, Montreal, have put in 75 lights; Chatham, N. B., has put in 200 20-c. p. municipal lamps. Thompson's shoe factory, Montreal, is running a 200 light plant, supplying themselves and others.

Mr. M. D. Bow has succeeded Mr. Lawson as Canadian agent of the Edison company. Mr. Lawson, however, remains with the company in charge of the factory at Sherbrook.

In the suit of the Edison company, *vs.* the Royal company and others, on the question of infringement, the Edison company have asked a delay until the 10th of November, when the case comes up for decision.

The Royal Electric Co., are making vigorous preparations here for the establishment of a 1000 light alternating plant, and have the foundations under way for a 1000 h. p. station. Only a portion of this capacity is to be used immediately.

The Montreal city authorities sometime ago took up the matter of lighting the city from one or two stations to be established by the corporation. Mr. Badger, city electrician, has handed in his

report and an estimate for 800 arcs and 500 incandescent lamps, of 32-c. p., and places the estimated cost at $280,000 for the erection of a complete system in two stations, including electrical and steam plant.

Much regret and sympathy is felt here on account of an accident occurring to Mr. Sise, at Halifax. While he and a friend were driving in the evening, they were run into by a farmer's wagon. Mr. Sise was thrown out, and his friend also, who, falling on Mr. Size's breast, broke a rib. Mr. Sise arrived home a few days ago, and is now progressing favorably. His friends hope to see him about again as usual very soon.

Mr. T. D. Lockwood was in town a few days ago on a semi-holiday (he never takes a whole one) and a trip through Quebec. Mr. Geo. Manson and Mr. Henry D. Stanley, also favored us last week by a flying visit.

The Federal Telephone Co. have nearly all their poles placed in position and have begun to string cables. Progress is slow however. If they are ready in the spring as is now promised, much will have to be accomplished in a short time.

Mr. W. R. Kimball, of the Royal Electric Co., began recently a series of lectures before the Young Men's Christian Association class. He is a young man of marked talent, and those who have the opportunity of attending, will be well repaid, as he intends illustrating his lectures by numerous experiments.

MONTREAL, October 19, 1888.

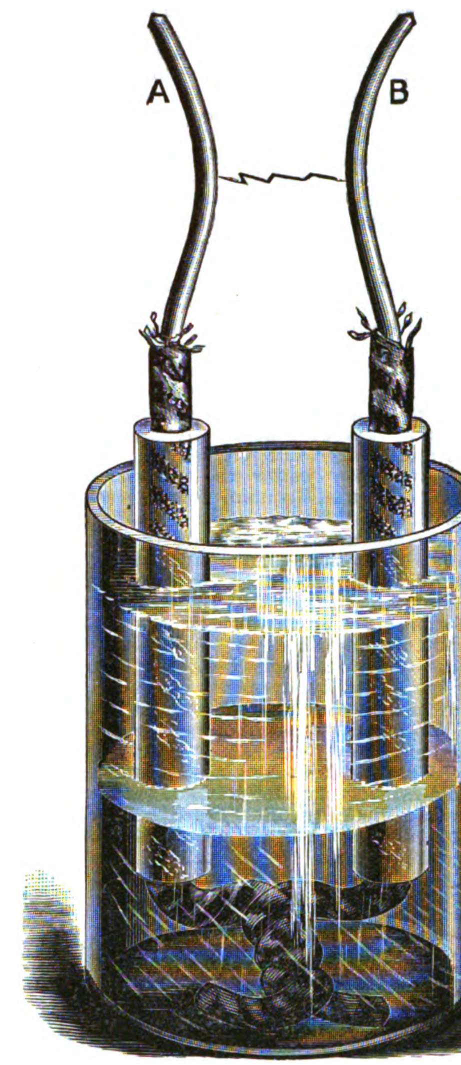
DISRUPTIVE DISCHARGES IN UNDERGROUND CABLES.

[99].—At the meeting of the National Electric Light Association, held in New York some six weeks since, Mr. E. G. Acheson read a paper touching the "determination and the cause and cure of the frequent puncturing of the insulation, especially at the terminals, of lead-encased conductors, when carrying high potential currents." As Mr. Acheson's paper has had a pretty extensive publication in the electrical journals, I offer a few remarks on the determination, the cause and the cure of the evil discussed in it. Mr. Acheson speaks of the trouble as "disruptive discharges." In coiling and uncoiling lead you are liable to open pores. As lead tubing is coiled, the outer surface of the tube forming the circle is elongated and the inner surface compressed, and this condition is enhanced by the comparatively rigid nature of the cable or conductors inside. If the insulation consists of paraffine, which is all broken by the coiling and uncoiling, and a "pinhole" happen to be open to the paraffine, moisture penetrates the lead and paraffine also, and gets to the conductor. If instead of paraffine a mixture of rosin and rosin oil is used, and moisture gets to the mixture, it stops there, because the mixture is semi-liquid and heavier than water; but as lead tubing is drawn over the cable it comes in contact with its textile covering inside; now if moisture reaches the textile covering, the covering will absorb it and it makes no difference whether you use paraffine, asphalt, rosin and rosin oil, or any similar substance.

There is no way of making any vegetable fibre moisture-proof except by surrounding it by some substance that is itself moisture-proof. If we take a piece of lead-encased cable, make a hole no larger than the point of a needle and immerse that portion in water, if the hole goes no farther than to reach the paraffine, it will go to the conductor and the insulation is impaired; similarly if the insulation consists of rosin and rosin oil, the moisture will reach the mixture, but goes no farther, the insulation is not impaired; but if the pore is open to the textile covering which is liable to be in direct contact with the lead, the textile covering will absorb the moisture and insulation is impaired. I have shown this by experiment many times.

Many attempts have been made to lay lead-encased cables across rivers, and every one, to my knowledge, has proved a failure where the insulation consisted of paraffine, although the lead was served with hemp saturated with tar, and further protected with an armor of iron wire; but when rosin and rosin oil were used, and the lead served with a similar outside sheathing, better results were obtained. These cables were used for telephone purposes where feeble currents are employed; how much more liable are such cables to fail when currents of a high potential are used? How many lead-encased cables have failed in this country when used for telephone purposes! Can it be said that they were destroyed by disruptive discharges when they were provided with lightning protectors, point discharges and plate discharges?

Let this be illustrated by an experiment:—A glass jar is about one-third filled with a mixture of rosin and rosin oil, two cotton covered wires are twisted together and the ends separated, as shown in the bottom of the jar; the wires are heated in the mixture to 350 F. before being immersed, then two glass tubes are drawn over the wires, the tubes extending into the mixture below; we then turn water on to the mixture, filling a portion of the jar, as shown in the figure. The wires are supposed to be No. 16 gauge insulated to one-eighth of an inch diameter. Although



the wires are separated from each other where twisted by less than one-eighth of an inch, if we apply the two poles of a Holtz machine at the ends, A and B, we can pass a spark between the bare portions of the wire two inches in length, before the current can be made to pass through the covering of the wires when twisted together. It will be seen how easy it is to protect the insulation from disruptive discharges. Iron pipe is a thorough and radical "cure" or rather preventive of "pinholes." If we substitute paraffine in place of rosin and rosin oil mixture, the water penetrates the paraffine although it has been allowed to cool and become seemingly solid, the insulation between the wires fails.

The cable that I laid for the Pennsylvania Railroad Co., over a year since, embodies these principles; it contains 53 conductors. May 5, Professor Kendall gave the average insulation over 4,000 megohms per mile. Every conductor is in perfect condition. The professor will make another test of the conductors soon, and I will send you the results. DAVID BROOKS.

PHILADELPHIA, October 16, 1888.

.... WILLANS & ROBINSON have actually delivered from a dynamo one kilo watt by the consumption of two pounds of coal per hour, or by the condensation of 20 pounds of steam.—*W. H. Preece.*

.... SPLENDID as are these most successful uses of water power to actuate distant electromotors, it is but a stray stream here and there that has yet been utilized, and countless wealth is still being squandered in all the torrents all over the world.—*Professor Ayrton.*

LITERATURE.

REVIEWS.

The Elements of Electric Lighting, Including Electric Generation, Measurement, Storage and Distribution. By Philip Atkinson, A. M., Ph. D. D. Van Nostrand, New York, 1888.

DR. ATKINSON has written a book that contains for the most part the kind and amount of information on electric lighting and its allied topics that would be desired by, and be useful to, general readers who have not time for bulky octavos, but like to know something accurately about an art and industry so prominent as that which gives the title to this small volume.

In the introduction the author says he desires to set forth "the various facts pertaining to electric lighting in plain language, devoid of technicality and perplexing mathematical formulæ, from which business men, mechanics, and those who have the care and management of dynamos and lamps, as well as general readers, may gain a knowledge of the principles and construction of the apparatus by which this light is produced, and of the nature of that invisible, intangible agency which is its prime cause."

Chapter i. is devoted to the question, What is Electricity? Dr. Atkinson is very confident that it is a mode of molecular motion, and in 13 pages sets forth the reasons for his belief with much cogency and in a very interesting manner. Chapter ii. begins the subject proper of the book, and as befits a work on electric lighting as a commercial art starts off with "Principles of the Dynamo." Chapters iii. and iv. are devoted to "Alternate Current Dynamos" and "Direct Current Dynamos" respectively. "Electric Terms and Units" are treated in chapter v. Perhaps it would have been better to introduce this matter before the chapters on the dynamo, for the sake of readers unacquainted with the terms and definitions employed in describing the construction and mode of operation of the dynamo. A fuller and more elementary explanation of the principles of magnetic induction than Dr. Atkinson has supplied would be to the advantage of the uninstructed reader in acquiring a clear notion of the source of the electric current in a dynamo. Chapters iii. and iv. are amplified by illustrated descriptions of machines as made by several leading electric light companies, fairly presenting the several types now in commercial use.

Following the treatment of the dynamo, a chapter each is given to the arc lamp and the incandescent lamp. Chapter ix., "The Storage Battery," and chapter x., "Electric Distribution," conclude this useful and readable book, with a brief but reasonably comprehensive and satisfactory sketch of the growth and progress of those branches of electric work. Dr. Atkinson's manual can be sincerely commended to the attention of the classes of readers addressed in his introduction.

NEWS AND NOTES.

THE TELEPHONE.

THE ordinance authorizing the Cleveland Telephone Co. to place its wires about the Public Square, and in the down-town streets underground is now a law, and the company will soon begin the work of laying the conduits.

THE BELL TELEPHONE CO., of Philadelphia, has commenced the work of putting their wires underground. Lead covered cables are laid in wooden boxes under the streets, and the wires are carried to large poles in the centre of each block, and from there they are distributed to the several subscribers in that block. A large trunk line is being laid in Market street, from river to river. Other lines branch off north and south on each of the main streets. In nearly all the blocks, small streets and alleys provide convenient centres on which to erect the distributing poles. By this system all streets will be freed of wires, as well as roofs of houses, and the network of distribution in back yards and small streets will be so small as not to be objectionable. The ordinance authorizing the laying of these underground wires and erection of poles requires the removal of all overhead wires within five years, but the company expect to complete the work sooner than that.

THE Philadelphia *Record*, of October, says, that connection has successfully been made between Philadelphia and Portland, Maine, a distance of 600 miles, which may be considered another long-distance triumph.

THE Wilmington *News*, Delaware, states that a telephone wire has been erected from the Lewes life station to the station at Chincoteague. Through the communication thus established, many lives can be saved in case of a disaster.

IT is reported by the Montreal *Witness*, of October 4, that the telephone was put to a novel use in Toronto. A citizen who had been summoned to appear at the police court for breach of a by-law finding that he could not appear in person, telephoned the fact to headquarters, admitted his guilt, and was fined $1.00 and costs through the same medium.

THE following is reported by the *American*, of Nashville, Tennessee. A council committee has just framed a new bill, relating to the Cumberland Telephone and Telegraph Co. It practically places the company under control and direction of the board of public works. The company must pay a yearly tax of $1.00 on each set of instruments in use, and must give a bond of $25,000 to indemnify the city against any loss. The bill has passed second reading.

INJUNCTION SUIT AGAINST THE CUSHMAN COMPANY GRANTED.

Shortly after the termination of their suit against the Cushman Telephone Co. (an abstract of which appeared in the ELECTRICAL ENGINEER for September), the American Bell Telephone Co. brought an injunction suit to restrain the Cushman company from continuing the rental, sale and operation of instruments in the State of Indiana. Judge Blodgett rendered his decision October 29th, granting the injunction asked for; not to take effect, however, until January 1st, 1889.

The defendants claimed that the Bell company had withdrawn its instruments from the state upon the passage of a law limiting the rates. Upon this point the court ruled that the fact that complainant's licensees or grantees have withdrawn their telephonic accommodations does not furnish any excuse or any defense for the infringement of these patents by defendants.

THE NEW YORK ELECTRICAL SOCIETY.

A meeting of the New York Electrical Society was held October 24, in the lecture room of the laboratory of Mr. Thomas A. Edison, at Orange, N. J. A paper was read by Mr. A. E. Kennelly, Mr. Edison's chief assistant, upon "Electrical Measurement." Mr. Kennelly's remarks, although largely extemporaneous, covered a wide range of experiment and illustration. He exhibited the new "Ergmeter," of Professors Ayrton and Perry. At the conclusion of Mr. Kennelly's remarks an exhibition was given of the phonograph, after which several of these instruments were placed at the convenience of the society and its guests. About 250 persons were present. The evening was very enjoyable to all present.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

SPECIAL MEETING, OCTOBER 9TH, 1888.

Discussion of Mr. F. J. Sprague's Paper on Municipal Rapid Transit.

THE series of special meetings for the season of 1888–89, was begun October 9.

The meeting was called to order at 8 P. M., by Mr. Ralph W. Pope, secretary, at the house of the Society of Civil Engineers, 127 east 23d street.

Mr. Pope—In the absence of the president, the indisposition of one of the vice-presidents and the desire of another to be excused from service this evening, it will be necessary for you to select a chairman.

On motion of Mr. Jos. Wetzler, Mr. G. M. Phelps was chosen chairman for the evening.

The Chairman—Gentlemen, I am indebted to you for the compliment of being called on to preside to-night. I will ask the secretary to state the programme for the evening.

The Secretary—As most of you are aware, the programme of the evening, as stated in the call issued, is the discussion of the paper on "The Solution of Municipal Rapid Transit," read by Mr. Frank J. Sprague before the Institute, June 19th.[1] On account of the length of the paper it was considered wise to defer the discussion until this fall, and in considering the advisability of taking it up this evening the council decided that as we had a member in Richmond, who was on the spot and has taken great interest in the work to which Mr. Sprague referred in his paper, and who is in an entirely independent and unbiassed position, he would probably be able to give us some valuable information in regard to the work done. In addition to Mr. Leonard's contribution to the discussion, I have a note from Mr. Almon Robinson, of Lewiston, Maine,[1] in regard to gearing, which will also be read.

Mr. M. B. Leonard read his paper entitled "Some Objections to the Overhead Conductor for Electric Railways." (See page 520.)

The Chairman—Gentlemen, if it is agreeable to you, I will now ask the secretary to read Mr. Robinson's paper, as Mr. Robinson, I believe, is not here. Then, after the reading of the papers, the discussion will be open.

The secretary then read Mr. Robinson's paper, "Note on Gearing for Electric Railway Motors." (See page 522.)

Mr. Pope—I might say, in connection with this note of Mr. Robinson's, that he was present at the meeting at which Mr. Reckenzaun read his paper on "Electric Street Cars, with Special Reference to Methods of Gearing," September 20, 1887,[2] and he told me personally that he was much interested in the subject of frictional gearing, and he felt that it had got a black eye from Mr. Reckenzaun's paper.

The notices which were sent out announced probable contributions to the discussion by Mr. Mansfield and Mr. Blackwell. I have a letter of regret from Mr. Mansfield, announcing his inability to be present, and I am not certain that Mr. Blackwell is here this evening. There are no other papers.

The Chairman—Is Mr. Blackwell present, if so we shall be very happy to hear from him. (Mr. Blackwell was not present.)

The interesting paper of Mr. Leonard and the note of Mr. Robinson, seem to afford very good starting points for discussion, and the question is now open for any gentleman who wishes to speak. I see a number of gentlemen more or less intimately connected with electric street railways and electric power; we shall be glad to hear from any of them.

Mr. Ries, of Baltimore, is present with us this evening. Has he any remarks to make?

Mr. Elias E. Ries—Mr. President and Gentlemen:—It is not often that a paper upon so broad a topic contains so much solid information as the one that we are here to discuss. Mr. Sprague deserves to be congratulated upon the ability and thoroughness with which he has presented the subject, and I take pleasure in adding what little I can to the discussion of such of its features as seem to me to require more elucidation.

The paper may be divided into two parts; one dealing purely with the "Municipal Rapid Transit Problem" as determined by the conditions that obtain in New York city, and the other relating to the construction and operation of ordinary electric street railways. I shall take up the latter phase of the paper first, and then, if time permit, will have a few words to say on the general subject of rapid transit as applied to the requirements of New York city.

Mr. Sprague refers to several methods of converting the momentum of a train or car into useful current; one of these consisting in converting the propelling motor or motors of a train into braking generators when running on a down grade or coming to a stop, and returning the current generated back into the line for the purpose of assisting other motors. This method necessitates raising the counter E. M. F. of the motor until it exceeds the direct E. M. F. of the line, and as this latter is 400 or more volts, it will be apparent that only in a few exceptional cases is the train energy or momentum sufficient to develop in the motor or motors anything above the initial E. M. F., for any appreciable length of time. During all this period the energy of the train is simply being expended in overcoming the direct E. M. F., or, in other words, in preventing the entrance of the line current to the motor by developing the 400 or more volts necessary to oppose it; a result that can be as readily obtained without the expenditure of this energy by simply opening the motor circuit. The practical effect of the method referred to will be to partially brake the train, but except in a few extreme cases the line current derives no benefit or assistance therefrom. There is, however, another and more economical method of conserving the surplus energy of a railway train, which avoids the loss of the bulk of this energy and at the same time permits of the utilization of this energy *upon the train itself* at times when it is most required. This method, as developed by me some time ago, consists in the employment of a secondary battery so arranged as to be connected with the motor circuit whenever, as in stopping or descending a grade, the connection between the line and the motor is interrupted, and the latter is in condition to generate a current under the influence of the momentum of the train. The battery cells are connected in parallel or multiple series order during the time when they are in circuit with the generating or braking motor, so as to oppose an electromotive force of only a few volts to the charging current, thereby making the momentum of the train or car instantly available for changing the battery, this changing process continuing until the speed of the armature has been so reduced by its own braking action upon the train or car, that it is no longer capable of generating the few volts necessary to effect the entrance of its current to the storage battery. In this arrangement an automatic potential switch, of special construction, prevents the closing of the charging circuit until the E. M. F. of the current from the motor exceeds that of the battery, when it occurs almost instantly, and breaks the connection when the E. M. F. of the charging current falls below that of the battery, the entire arrangement being so simple as to require no attention whatever on the part of the motor man. The current thus reclaimed on descending grades and stops is, in the Ries system of electric railways, employed to assist in operating the train or car when ascending grades and when starting. The battery, or such portion of it as may be set aside for operating the motor or motors, is of course discharged at a higher voltage, and can be utilized for electric lighting and all other train purposes to which it may be applicable. It will thus be seen that a two-fold effect is obtained, since the surplus energy of the train, which under existing conditions is ordinarily wasted, is not only made to stop the train without the use of friction brakes, but the energy consumed in stopping the train is, with the exception of a very slight loss in conversion, etc., almost entirely recovered and turned to useful account. Mr. Sprague has stated, in referring to the operation of the New York elevated railway system, that 59 per cent. of the power expended by the locomotives on a round trip is used in starting, 24 per cent. in lifting, and only 17 per cent. in traction. That means that 83 per cent. of the total power expended upon the elevated railway system in this city is consumed on account of stoppages and grades, of which nothing is recovered, but on the other hand, the waste is augmented by the use of further steam to apply the brakes. If only one-half, or say 40 per cent. of this wasted energy can by the method above described be recovered, of which I have not the slightest doubt, the value of electric traction for roads of this character, over that at present used will be apparent, from this point of view alone.

Another matter of considerable importance is whether one or two motors are most advisable for street car work. I am myself in favor of employing but a single motor directly geared to both axles, and it is the universal opinion of electricians and engineers that in a case of this kind a single large unit is better than two or more smaller ones, and this is especially true in regard to street car motors. A great deal has been said about the difficulty of making satisfactory connection with both axles from a single driving source, but this can be overcome, and I may say I have devised a method of doing this which avoids most of the difficulties heretofore encountered. It is a question to my mind whether Mr. Sprague's assertion that independently driven axles necessarily give better track adhesion, can be sustained. In fact, it seems to me that the reverse is generally the case. There can be no doubt, as Mr. Sprague states, that independently driven axles will slip until they get the best grip, but it is also known that a slipping wheel or pair of wheels will readily continue doing so under the influence of the acquired impetus and the rotative strain exerted upon them by the motor. However, in ordinary street cars the load is constantly shifting from the forward to the rear axle, and vice-versa, due to the lurching of the car and unequal distribution of the weight or load. Therefore, supposing a car to be slightly overcrowded at its rear end, the forward wheels must necessarily slip, and the motor driving them will run light for the

time being, leaving the rear motor, which was designed to do but half the total work, to do it all, and subjecting it to an enormous electrical and mechanical strain.

I have given this subject considerable attention, and have come to the conclusion that for street cars of ordinary construction the axles should *not* be independently driven, but should be directly connected with each other, preferably through the armature shaft of the motor itself, whose weight is equally borne by both axles. In this manner the combined tractive effect of all the wheels may be obtained in unison, which will reduce the tendency to slip, and the load upon and work done by the motor will be a constant quantity irrespective of the shifting of the load. For pivoted truck or eight-wheeled cars the objections to independent driving do not so seriously apply, but the advantages of a direct connection with both axles of a truck are even more apparent for other reasons.

I thoroughly agree with Mr. Sprague on the matter of making each car of an elevated train its own motor, provided the motors of the entire train are controlled from a single point. In all cases where stops are frequent this plan possesses numerous advantages, but for trunk line railways having substantial roadbeds a single large motor, or perhaps a front and rear motor suitably connected, but capable of independent operation when separated, will probably always be found preferable to a number of small ones.

One thing that struck me as very peculiar in connection with the Richmond road, was that an electrical engineer of Mr. Sprague's ability and experience should so utterly abandon all measure of precaution for the safety of his passengers and the public at large as would seem to be indicated by his employment of the track rails and ground as one side of the circuit, instead of using a double overhead conductor. This is the more to be wondered at when it is shown by Mr. Sprague's own description of the elaborate and extensive means employed for connecting the track rails and re-enforcing them by separate wires to insure perfect connection with one another and with the ground pipes, etc., that aside from its danger this plan is considerably more expensive than a second overhead wire and double trolleys would be. I can only explain this action on the part of Mr. Sprague by assuming that he has found the track return necessary to enable him to ascend the steep grades of the Richmond road, by reason of the increased tractive adhesion obtainable due to the passage of the propelling current from the wheels into the rails. If my memory serves me rightly, it was not very long ago—in his address before the American Street Railway Association at their Philadelphia convention last October,—that Mr. Sprague stated that on roads having grades of more than 6 per cent. he proposed to attach a hill horse to the motor car! Whether he intended this as a parting tribute to the usefulness of the patient and long-suffering car horse who has so faithfully served the public, I do not know; but at all events he stated that he did not believe it possible for a self-propelled car to get up the hill in any other way. This was some time after I had announced the results of some experiments I had made, both with the electric current and electro-magnetism, in which I was able to show and demonstrate that the tractive adhesion of driving wheels could be very largely increased by these means—sufficient, in fact, to enable a motor car to ascend a grade much steeper than any yet surmounted.

However, I might state here that this increased tractive adhesion can be obtained without subjecting the public at large to the danger incident to the use of a ground return. Every electrician knows, and perhaps no one better than Mr. Sprague himself, that a ground on any circuit multiplies the danger of leakage, and on an electric railway circuit carrying a pressure of 400 or 500 volts should never be permitted. In the Ries electric railway system we have a cheap and simple method of increasing the tractive adhesion without employing the track rails as a return, which can be applied to any electric railway operating on the parallel system. This consists simply in passing the current from the conduit or overhead conductors, after it leaves the motor, to the forward car axle, which, of course, is insulated from the car body, and to connect the rear axle, also preferably insulated, to the negative or return conductor. In this way the current, after passing through the motor, must traverse that portion of the track rails lying between the two pairs of wheels, which latter are thus included in the circuit. The portion of the track rails traversed by the current will not act as a ground, but simply as a good conductor inserted in the branch or loop that feeds the motor. This is only one of a number of ways in which an increased tractive adhesion may be obtained, but I prefer in most cases to employ a current that is entirely independent of the motive current and of such quality as to produce a very much greater and at the same time a variable tractive effect. I may say that we are at present engaged in applying this system to an ordinary steam locomotive, on a prominent railroad, and if the results obtained prove to be anywhere near what we have reason to expect from certain experiments made on a smaller scale, I shall hope to be able to show you a very decided increase in its pulling capacity, and to effect a considerable saving in the cost of operating the road.

With reference to the ideal method of braking referred to in the paper under discussion, I might state that a modification of our electro-magnetic traction apparatus has been applied by us for this purpose. In this we magnetize the car wheels as in our traction apparatus, but in addition provide an electro-magnetic braking arrangement, the whole being so arranged that when the brake circuit is closed, not only are the brakes applied to the tread of the wheels, but the co-efficient of friction between the wheels and the track rails is greatly and simultaneously increased, thereby enabling us to apply a greater brake-shoe pressure than now possible, and yet prevent the wheels from skidding upon the rails. This method of braking is effective in almost any weather, and is applicable to street cars or to railroad trains. In cases where braking is effected by utilizing the motor or motors as braking generators, as before explained, this system is still available and only the traction circuit needs to be established between the two axles of each truck to render it effective. This, in my opinion, constitutes the ideal method of braking, and before very long I hope to be able to show you such a system in practical operation.

Mr. J. M. Pendleton—I rise to make an inquiry. I have heard several eulogies on the Sprague motor that is used in Richmond, and I would like to inquire whether the motor used in Richmond has anything but a plain, series-wound Siemens armature? If it has not, it seems to be a very old form of motor—one that certainly has not got anything to give it a title except the maker's name. I think we ought to give to those who have invented certain forms, the credit of inventing those forms. A short time ago I looked over a work lately published by Mr. Silvanus P. Thompson—a very excellent text book, and one that must form a very valuable addition to any electrical library. In that work, replete with everything that an electrician would value, I found on one of the pages a very strong endorsement of the Immish motor—a motor that is well known in England, and one which it has been attempted to introduce in this country. To my surprise I found my own name and that of another inventor mentioned on that page as having invented a motor of a form discarded by Mr. Immish. Now, it struck me at the time that it was a misfortune that so valuable a book should contain anything to mar its high merit. A little motor intended for a very small use—a sixteenth of a horse-power—was not a fit subject for such a remark; and it naturally occurred to me to ask what is there in Mr. Immish's motor peculiar to Mr. Immish? It is certainly nothing but a Siemens armature in a two-pole field, and there was nothing indicative of the inventor about it, and the name of the motor certainly belonged only to the manufacturer. Now, in these motors we know that Mr. Sprague has spent a great deal of time and given a good deal of study to certain lines of regulation in motors, but they are certainly not adapted to car purposes, and if a plain series motor is put upon a car, why should we call it one thing or another? Therefore I think the inquiry is pertinent: Is there anything in the motor except that it is a series-wound motor, such as we have been familiar with a great many years, even before we knew the names of a great many manufacturers who certainly cannot claim the invention of a motor of that class?

Mr. C. O. Mailloux—It was at first my intention not to say anything in the discussion this evening, but I think it is my duty to speak disinterestedly of the matter brought forward by Mr. Pendleton. While it is true that there are very few types of motors existing, and that in fact the question of selecting a type, in the mind of an electrical engineer who is about to design a motor, comes down to but two forms, strictly speaking, yet it does not appear to me to follow that we should be compelled to give to the motor designed merely the name of that peculiar form. We have only to look into other fields of engineering—and I know no better example than this which he mentions—to see how the names go. If we were to give absolutely to Cæsar what is his, the engines that we use to-day would be known by the names of people who lived before we were born. As a matter of fact, while James Watt may have done a great deal for the steam engine, yet it does not follow that he is entitled to the full credit of the steam engine, because if we were to place the engine designed by James Watt in contrast with the engine designed later by Corliss, we would find great differences; and if you would come down still further and compare it with the triple expansion compound engines now being made, you would find still more marked differences. Yet, strictly speaking, they are all of the same type—a reciprocating piston taking steam at both ends, and the variations merely come in the form of valve motion and various other details. Now, the criticism made by Mr. Pendleton would imply that in designing a motor you have only to look at a book and find a picture that suits you the best, and then if you decide that it is to be a series motor or shunt motor, you simply go to work and have it made. Now, to us who have been through the mill—who "have been there," as the saying is—we know that the process is far from being as easy as that. We know that there are very intricate calculations to be gone through, and calculations that must be gone through in very adverse and trying situations, inasmuch as, so far from the art being entirely known, we are in fact only on the dawn of knowledge. In other words, the data that we have to work from, the facts, figures and principles, are very incomplete, and we must go often into the domain of the hypothetical to help ourselves out. Now, I think that so far from disparaging the efforts of people in designing, we should, on the other hand,

certainly give them credit for what they have done, because we ought to realize the amount of study, hard work, experimenting, and oftentimes expense, which has been necessary to enable them to arrive at those results.

I claim that if Mr. Sprague, or anybody else, is able, as an electrical engineer, to combine material and to mould it so that it shall accomplish results that nobody else has accomplished, then he is perfectly and fully entitled to have the motor known by his own name, just as much as a steam engine is known by the maker's name.

Mr. Pendleton—My friend, Mr. Mailloux, has not directly replied to my question. In the matter of preparing the work of others, where one has really become an inventor, has become a student in certain styles of regulation and has appropriated to himself other patents and other matters, he is entitled fully to the benefit of his work and to have it known as his work and his style of apparatus; but where he departs from that to another type, why should that name be continued when it is nothing of his work, and belongs to somebody else? That is the matter I spoke of. I did not intend to throw a bombshell into the controversy. It was a mere inquiry. I heard the motor lauded, and knowing the work of Mr. Sprague, his very intelligent, and you may say audacious, attempt to overcome the natural difficulties of a city having the grades of Richmond, I think he is entitled to the highest credit; but at the same time I thought that it might be well to distinguish what belonged to one and what to another.

The Chairman—I do not think there is any danger of Mr. Sprague's reputation for his distinguished service in the matter of street railways suffering any harm in a meeting of the Institute of Electrical Engineers; but I think we might better return now to the discussion of the subject of the evening—Mr. Sprague's paper, and the papers that we have had read in discussion of it here to-night.

Some interesting points were noted by Mr. Leonard, particularly in regard to what he considered the deficiencies of the overhead system and the relative merits of the storage battery. I hope Mr. Sprague will speak to us at this juncture.

Mr. F. J. Sprague—I am rather glad that some argument has come up in the discussion of the paper. I think possibly I am in a position to correct some of the impressions which have been received so as to remove doubts about certain points. I do not care to here enter into a discussion as to whether any work that I do shall go under my name or in some other man's. So far as the difference between the Sprague motor in Richmond and the Siemens machine is concerned, either Mr. Pendleton does not know what the Sprague motor in Richmond is, or what the Siemens motor is. We use in Richmond a double commutator machine which is unknown to-day to any one except those whom I have taught. Its plan of winding has never been published or described. It is, as I say, unknown except by the employés of my company, and if there is any question as to the similarity of that winding to some other, I have not the slightest objection to giving the necessary diagram of connections. It is a series machine, but a series machine which has some peculiar characteristics. It is wound with three sets of coils, and the peculiarity very largely consists in the method of connecting and certain switches, by which the coils in these machines are commutated and reversed, their field magnetization and their current varied at will, through progressive changes, by means of which, when desirable, we are enabled under various loads to maintain an almost absolutely constant field, while the current may vary 300 per cent. That has never been done with a motor before; that is, to so regulate the field that, with a variation of 300 per cent., a perfectly constant field will be maintained. This field connection is somewhat peculiar, so much so that it would be useless for me to attempt to describe it now, although I shall take occasion to publish a description of it in the near future. There are, however, some characteristics of motors other than the mere winding of the armatures or fields, or their regulation, which are essential for street car purposes. It is, as Mr. Mailloux says, a question partly of proportioning, partly of calculation, a putting together of those things which you have at hand to meet those conditions under which you have got to work. Two years ago, I think I may fairly say, such a problem as equipping the Richmond road, with its abnormal conditions, with the circumstances of manufacture which we had to meet, and in the time that was given to us in the then undeveloped state of this art, would have been looked upon as somewhat preposterous. I am frank to confess that had I known what I had to go through, I would, perhaps, have had neither the necessary courage, time or patience, or have cared to have risked the money which I did. I have spent in Richmond $150,000, and I have learned something. While I do not care to state all I learned, I have taken advantage of it in our future work. A great many of the principles of regulation that have been associated with my name are not characteristic of the Richmond machines. They are designed for other purposes. Now, referring to Mr. Leonard's paper, a great many of the deficiencies he speaks of exist in Richmond, and unless the machine were of superhuman design, they must exist there. A year ago those machines were put in in a great hurry. The maximum normal capacity that they ought to run at is about 7½ h. p. Very frequently they have been called upon to develop 10 or 11 h. p., an increase of about 50 per cent. In the nine months during which this road has been in actual operation, and it has run nearly half a million of miles and carried millions of passengers, not one working car has ever been inside of a closed shed. They have been housed in the street. The photograph which you have in the report of the paper read by me some months ago gives you some idea of where the cars have been kept. Of course, you are aware that when a machine is running it is exposed to more or less wear. It needs something of care and attention. A locomotive that makes two or three hundred miles is sent into a round-house, thoroughly cleaned and taken care of. It is a very good locomotive that will run with safety, and it is very poor management that will permit it to run more than three or four hundred miles without looking it over. The Richmond machines have run sometimes as high as 6,000 or 8,000 miles without being sent inside a covered shed. They have run without covers of any kind or character. They have run with six inches of water in the street and brake-beams running in the water, which was splashing on the motors. They have run until you could not tell what the machine was; until the accumulation of mud and oil and filth was of such a character that no other piece of machinery in the world would ever have run. I am not responsible, unfortunately, for the management of the Richmond railway. If so, we would not have the possibility of a number of cars lying in the car shed, so called, unfit for duty, after having been left in the streets during ten days of rain. The report from one of my own inspectors less than one week ago was that there was no more trouble in running a 40 car road by electricity than in one operating three or four cars. He is a level-headed, practical, cautious man, not given to strong statements, and very conservative in what he says or does. He says that out of 30 cars equipped for duty, there is no difficulty whatever in maintaining 29 on the road, if only that legitimate, ordinary, reasonable care is given to the machines which ought to be given to them; and that is the opinion of others who know the exact circumstances of the Richmond management, and the character of the attendance which the machines have had. There is no electric car in the world which has ever made anything like these records—from 80 to 110 miles a day on grades as high as 10 per cent., under loads 50 per cent. above the normal capacity of the machines in the hands of men oftentimes appointed for political purposes and not for intelligence, on duty 20 hours a day, and making 6,000 or 8,000 miles without going inside a shed to be cleaned off. I have been called a crank, and some time ago when I made the statement, as I did in the paper that was read here, that we would get to that position in electric motors in which it would be almost an impossibility in ordinary use to break them down, and that I proposed to wash the machines down occasionally, to get them clean, the remark was made: "Well, that fellow must be a damned fool." Well, I quietly pocketed that remark, and within the next thirty days or so we will have that machine out, and we will put one of those armatures that people have laughed about inside a barrel of water for 24 hours, and we will take it out and we will run it. There is no piece of electric machinery in existence to-day that will stand it. One of the difficulties which will occur on any road where cars are not properly and decently housed some part of the 24 hours is this: Cars that are running, of course, warm up, the pores open, they are ready for the absorption of any moisture. If it comes on a cold, damp, murky night, and these cars are left utterly unprotected, they will absorb more or less moisture. In dealing with the potential we are using there, of 400 to 450 volts on the line, you have a possibility of a short circuit in the coils. Some of the difficulties Mr. Leonard mentions, I think, he might have recognized as of a purely mechanical nature, or difficulties due very largely to lack of ordinary care. The breaking of a trolley wire, sometimes caused by a trolley catching in it, can be, of course, almost entirely obviated by one or two precautions; one of these is the non use of solder in the erection of a line. In putting up the Richmond line we used hard-drawn copper. Hard-drawn copper as it comes out of the mill has a remarkable tenacity, but when it has been handled, and when under the heat of a soldering iron it has been warmed up, you reduce it practically to the strength of soft-drawn copper; so that you will have at the point where solder has been applied a weak spot which entirely nullifies all your other precautions. In our future work, this trouble will be entirely removed, because we will not use solder from one end of the line to the other. The use of silicon-bronze or aluminum-bronze drawn for high conductivity and great tenacity, will likewise render less possible any accident due to the breaking of the wire. This wire can be drawn of from 100,000 to 150,000 pounds tensile strength to the square inch, and being put up without solder, I can see little possibility of that wire ever coming down.

So far as the use of poles is concerned, if you use a green pole, as the poles in Richmond were, it will bend; if improperly set in a clay soil, it will get out of position. If it is properly seasoned and set in concrete, there is no reason why it should give trouble. One of the most important roads that we have—we have some 26 or 27 now—is the West End road of Boston. Rights for an overhead system there having been granted within a few days, we are putting up a line that costs four times as much as the Richmond

line did per mile. I believe I said in my recent paper that the objection to overhead wires was entirely reasonable, because people did not put money enough into them. Having put all the money which I did in the Richmond road, I do not propose to put in any more there. On a new road, where I can make my own conditions before the contract is signed, I am willing to put in just as expensive a road as is desired. Instead of putting in wooden poles in Boston, we are putting in iron poles tested up to 1,400 pounds. Instead of setting them in clay, we set them in concrete. Those poles will not come down. So far as the span wires are concerned, there is no danger of their breaking.

As to the use of a single overhead line, that I know is a much discussed question. But I find the practice of most people is a single overhead line. There has been a good deal of "kicking" on the part of telephone companies. It has chiefly disappeared down in Richmond. The trouble is that the telephone companies had the earth and they wanted to keep it. (Laughter.) I can see no particular reason why a telephone company should not be required to exercise the same degree of care in putting up their lines that they would if the electric railroad were already in existence. The telephone man runs out his circuit as far as he can and charges as much as he can, and then, because some poor railroad company wants to put in some cheap and effective system of operating its cars, I do not think that it is quite just on the part of the telephone companies that they should raise their hands in such holy horror over the use of the earth circuits. Mr. McCluer, of Richmond, who was mentioned, had ingenuity enough to get out of his troubles. He took the trouble to run over his main telephone circuit, where they came near our wires, a single return wire, and he makes his telephone connections to that. His troubles have disappeared. I suppose it might have cost his system a few hundred dollars. If he objected to paying that, I suppose we could have paid it for him, but he has, as I say, overcome his troubles by the most trivial possible expense. If that is the only objection that telephone companies have got, it is not a legitimate objection. So far as the burning out of their exchange is concerned, I will have to correct Mr. Leonard in that. At the time one of their decayed poles fell down and landed three or four hundred wires on top of our lines, the dynamos were not running at all. This is the only pole breakage I know of. We have burned out some of their instruments, but that is simply because we took a reasonable amount of precaution, and they did not. They got their wires across ours, and they got the worst of it. The great trouble with telegraph and telephone business is this: the thousands of miles of dead wires hanging down in the streets and over the house-tops. A man who has a telephone does not take the trouble to take down his telephone wire after he has discontinued the service. There is no æsthetic sentiment in a telephone company. They are perfectly willing to say, "Here, you electric light people and you electric railway people are causing a great deal of trouble to our customers." If they would all join hands in an equitable arrangement, as some of them have, they would have little cause to complain.

A criticism has been made about the use of two machines on a car. I have spent half an hour trying to get the length of this room with one motor on a 6 per cent. grade, under a condition which happened to give a slimy surface on the rail, and I have seen under the same conditions, on a 10 per cent. grade, on a worse track, two motors handle the heaviest loads. It is not merely because the wheels can get a better grip—you have got your total weight available for traction. The forward wheels can also, in case of an emergency, travel faster than the rear wheels. That has been done, even on a level, and has the advantage of breaking up whatever obstructions there are on the track and leaving the track perfectly clear; if you put between your wheel a broom or brush, you have excellent traction. It could not be done by gearing both wheels to the same motor, simply because you could not get that independence of grip that is necessary. Running both pairs of axles requires certain devices, the use of which, in view of existing street car practice in the matter of constructing running gear, I do not think is advisable. There are some 40,000 or 50,000 cars in the United States, and there are one or two settled principles in them; one is, perfectly independent action of the axles. No four wheels on a car are of the same diameter; they are never cast absolutely alike; they do not run necessarily on the same tread. Any difference in the level of the streets will send the weight of a car down on one side. In fact, it seems to me, in the face of all I have seen, almost trivial to make any objection to the independent driving of two axles. I admit it is cheaper to build one machine to put on a car, but you can build two smaller machines of the same capacity. Space in a street car is a matter of considerable importance. You want to get large power on a car to handle heavy loads, but you have got to have it in comparatively small space.

As to keeping a trolley on a wire, I am quite willing to enter into a contract to put a trolley on a car which never can come off the wire, and, in fact, some of our cars are now running with one man, and have to run with one man, simply because the railroad people won't pay an additional conductor.

The methods of getting rid of troubles have been, of course, subjects of a great deal of study. It was not possible, a couple of years ago, to look forward and face all the conditions that arise in practice. We electricians did not know enough about street car practice, and street car men did not know enough about electric railways, so we had to join hands with the street car men, and we had to put the cars and motors into the hands of ignorant men and meet those difficulties in order to know how to get over them. I think I may safely say that the road we will put in sixty days from now will bear about as little resemblance in details to the Richmond road as it is possible for any two roads to bear to each other, simply because of great improvements, not only in the motors, but in the gearing, switches, trolley work and all overhead superstructure.

A two-wire system requires from two to four times the weight overhead. Where we put a main conductor alongside of the street and reduce the trolley wire to a single one a fifth of an inch in diameter, that enables us to keep our structure in position a great deal better. So far as safety is concerned, the fact that a horse was killed in Richmond in the early days of running, is no criterion of it. Two wires are more liable to come down than one; but you won't get killed with 400 or 500 volts. I have several times taken that potential myself. We don't know whether the horse that was killed in Richmond broke his neck or was killed by electricity. He was boiled in order to get his skeleton; he did have a broken neck; it is not known whether that killed him. We had a mule there. (Laughter.) A man threw a lump of ice down on to our wires. The first mule—two of them were being driven by a darkey—ran his head into the wire and kicked, and finally fell down and lay on the wire. About half an hour after that they telephoned up to the general manager's office and said: "We have got a mule pretty well used up by a current; we want damages." He said, "All right." About 48 hours afterwards they sent up word that they did not think they wanted any damages; that mule seemed to be a great deal livelier than before. (Laughter.) In the case of the horse, that was gross carelessness on the part of everybody concerned—the conductor who broke the wire, the dog who investigated it, and the boy who rode the horse; but the only one injured was the horse.

The statement that the Richmond company has never been able to run more than 30 cars out of 40 is an error. The Richmond road never expected to run more than 30 cars out of 40. Its plant was built for 30 cars. A 40 car motor equipment had nothing to do with their line work, or their central station work. It is perfectly possible, as a matter of fact, to run the entire 40 cars.

As far as the use of the storage battery is concerned, I am just as anxious as anybody else that the storage battery should be a success. But it will never get on a car in Richmond when they have got to put 4,000 pounds weight on that car. They never will take 20,000 pounds weight up a 10 per cent. grade with a storage battery until it is in a good deal higher state of efficiency than it is to-day. We have, although not prominently connected with storage battery work, been experimenting for a long time. We keep a car on tap. We have had built hundreds of plates in the past year, trying to devise some means of overcoming some difficulties that exist in storage batteries now. We hope to have a normal capacity of discharge in, say, a 35-pound cell of not less than 75 or 80 amperes, and that they can stand 150. The resistance ought to be about one-third or one-fourth of the present storage battery. The plates will be practically indestructible; and, finally, it won't be a Faure cell. That is the sort of thing I am looking for. I do not know whether we will get it. The results, so far, have been very encouraging, but we never will attempt to climb a 10 per cent. grade with it, and we never will put it on the market until we know it is satisfactory. We will do our own experimental work. We expect to get the battery down so that not more than 1,800 pounds is necessary to handle the car under ordinary conditions. That will be something of an advance. The credit will not be mine, except that I have to pay the bills. Two years ago it was not possible to design a street car motor for entirely perfect work. I do not think enough was known about street car work. Certainly we are in a position to-day to design a great deal better machines than we did then. I shall have the pleasure of showing and explaining to this association, in the near future, our two latest machines—one about 7½ h. p., the other about 15—and their construction, I think, will appeal to street car people at least. I think by the time the Boston road is running, which will be in about five or six weeks, if Providence is not against us in the matter of the weather, we shall be able to show such improvement to the overhead line, as to its efficiency, economy and appearance, the character of the motors and the work which they will do, as will be a subject for mutual congratulation.

Mr. L. F. Lyne -I came here to-night principally for the purpose of being instructed.

I would like to ask Mr. Sprague if he really meant that a locomotive only runs 150 miles before it needs repairs? I think he meant 1,000. There are reporters here, of course, and if they get that wrong it will not sound well. I understood Mr. Sprague to say 150 to 200 miles.

Mr. Sprague—I might as well correct that impression at once, if you will permit me. I said it was not practicable in locomotive

work to run over 200 to 400 miles without the locomotive going under shelter and being properly oiled and cleaned; I did not mean going into the repair shop. What I say about the Richmond machines is this: They are not put inside of four walls; they are simply left in the streets. You cannot leave a locomotive or any other machine in the street for eight months under all conditions of the weather and have a machine that will not be apt to sometimes give you trouble.

I was quoted a little while ago as making a remark about hill horses. I was asked by a man who was interested in storage batteries—I believe he lived in New Jersey—if I would recommend in the equipment of a road which ordinarily did not have more than two or three per cent grade, but which did have in some particular places a heavy grade of eight or nine per cent., the use of motors which would climb a nine per cent grade? I said that as a matter of commercial investment I would say no. I said: "You will find it cheaper if, when you get to that eight or nine per cent grade, you take the trouble to put on a horse." That, certainly, was the intention of my remark.

So far as Richmond is concerned, I did not expect, in the first place, that we were going to have a ten per cent. grade there. Our specifications are for eight per cent. We have in some places the equivalent of a thirteen per cent. grade. We develop a remarkable traction, a traction which I never anticipated would be gotten out of a car, but no matter how we magnetized our wheels there, unless we drove both axles we never would get up these grades at all times.

Mr. Lyne—There are one or two remarks made by Mr. Leonard that I would like to refer to. The devices, so far as I have been able to discover, in transmitting the power from the motor to the axle of the car, have been in many cases obsolete devices. For instance, the grooved friction wheel has been used on the "Ben Franklin" that was tried on the 9th avenue road. That device was abandoned by engineers years ago, because the friction wheel caused flat places. If a sufficient pressure was not brought to bear on these wheels to bring it up to the maximum point at once, the surfaces would slip on one another, and a flat place would result. When the Fontaine locomotive came out we were led to believe that the whole railroad system of the country would be revolutionized in a few months by that engine. A certain few men predicted its utter failure, and it failed, principally in consequence of the tires getting flat places on them. As soon as they did get a flat place, they began pounding themselves to pieces, and the result was a dismantling of the whole affair. We know that the same occurs in locomotives in climbing grades. They slip, get flat places, and then the tires have to be turned off.

I am glad Mr. Sprague is here to-night and that he has so fully explained the difficulties which have been shown to exist in an overhead line. I fully agree with him that an overhead line must be put up as if it was never coming down. It is an old principle in railroading that each train should have its own independent motor, or in other words, if you have a cable or a wire upon which each train depends for its propelling power, if that line fails or any detail fails, you stop your whole road. Now, we have either got to have the overhead line as a permanent structure like a bridge or a railroad structure, or else you have got to resort to some means like the storage battery to give each train its own independent motor. Then, if it fails, you can throw it on one side and the trains move on.

I want to say just a word in reference to the storage battery. Now, I do not pretend to know very much about electricity, but there are a few things I have found out in the last few years, during which I have been connected with the electric lighting business. While I do not believe fully in the storage battery as it is constructed at the present time, I do know that it has been misrepresented in a great many instances. I have been told that it does not give as great an efficiency as is represented. Now, we have just tested some storage batteries, and we have got 80 to 85 per cent. of the charge back, and the failure of some of the batteries (we put in two series in which the plates failed at the end of about three and a half months) was due to fault in the material. We put two other series in the same place with improvements that I had suggested from the experience we had had, which consisted in placing the plates, instead of one-eighth of an inch apart, five-sixteenths of an inch apart. Then the scales, when they formed, went directly to the bottom instead of lodging across the spaces between the plates and short-circuiting. Now, we have got two series of batteries with four vertical strips of hard rubber between each pair of plates. That has been in use now about four months. We have not had any of them short-circuited, and those are the series that we tested the other day and got 86 per cent. We have no trouble whatever from those batteries; but with the others in which we used the old rubber plugs and plates about one-eighth of an inch apart, the scales were formed the full size of the little square, and they would tip over and lodge across the two plates. We had to keep at work at them all the time picking out the scales. The batteries, with those improvements, give us satisfaction. There is one other improvement which has been suggested and which I think will be adopted. The scales fall to the bottom, and lodge across the wooden bridge or support upon which the plate rests. That can be overcome by simply having one series of plates with a leg at each end resting on the bottom of the cell and the other series of plates resting on a hard rubber support running through the other series of plates and resting on the top of the plates that rest on the bottom of the cell. That leaves the space entirely clear for the scales to fall to the bottom. I have great faith in the storage battery, and I believe that a storage battery will be made eventually which will give a good efficiency and be much lighter than those now made.

Mr. Sprague—The question of depreciation of line is a question of construction very largely. It is certainly not a question of wear. A consideration of the actual time in which a wire is in contact will show this. With cars that are making two minute headway and running seven miles an hour, with a round trolley wheel, making contact on a round wire, we have almost a line contact, but call it an eighth of an inch contact. Any portion of the wire is in actual contact with the wheel less than one-two-hundred-thousandth part of the time; in other words, in continuous current contact, not over one hour in 26 years. Consequently the current ought not to rapidly wear the wire out, and it does not. In fact, the period in which any particular part of the wire is in contact is not over one-two-thousandth part of a second when the car is moving seven miles per hour.

The question of insulation, leakage and lightning came up a little while ago. It is a remarkable fact that lightning does not necessarily always follow the single overhead wire. We have had in Richmond quite a number of cases of the line being struck by lightning. Our ground circuit is made by three paths; two through the boilers and water connections, and a third through by a covered wire running about 1,000 feet on poles out, and direct down, to the track. We have had lightning come over that wire several times, and the statement of the engineers is that it is about an even thing whether it comes in on that line or the other one. It terminates in a well, and as a matter of scientific interest the engineers sometimes watch it as it goes into this well. So far as the leakage is concerned on that line, it can easily be reduced to an average of one-tenth or one one-hundredth part of 1 per cent. It has never been sufficient to cause the slightest interference with the operation of the wire except in the case of the short circuit. If existing, it can very easily be perceived by taking the reading of the ampere meter. The leakage is nothing so far as loss of power is concerned.

Mr. D. E. Lain—About the only part of the matter that I care to go into now is the means of coupling the motor to the axle. In Mr. Sprague's excellent paper he compares the method of direct coupling with other methods, as coupling by means of chain gear, friction gear, etc., in a way which, I think, was rather hard on the direct coupling. I have had some experience with some of these methods, and it seemed to me, as far as I have seen, that the method of direct coupling offers certain advantages which no other method offers. The easy motion and perfect noiselessness of the direct coupling certainly place it ahead of any other means; the simpleness, of course, in this method is greater than in any other. All the details are reduced to a minimum. The objection, of course, is that on account of the slow speed which the armature must necessarily make, running no faster than a driver, a larger machine is necessary. This may be an objection, and may not. In street railway work, where certainly not more than 10 h. p. is needed, where the whole equipment should not weigh more than say 5,000 pounds, when the car is loaded, the weight of the motor enters as such a part of the whole weight with the weight of a direct coupled motor, that it is not of such great importance after all. If the drivers be reduced to say 18 inches or thereabouts, a motor can be built that is not necessarily over 25 per cent. greater in weight than one using gear. This difference, this small difference, is offset by the greater efficiency of direct coupling over the gear. Of course, gear transmission is not possible where speed is reduced or changed from say 1 to 12 or 1 to 10 without some considerable loss of power. All this is saved in the direct connection where the loss by transmission should not be more than a very few per cent. So, of course, while we must all pardon Mr. Sprague for claiming that his particular system is better than any other, we are all willing to concede that this is due to the necessary qualities which go to make up a successful inventor, and also to the greater knowledge that Mr. Sprague has of his system than of any other; yet I think before the close of a year, at least before the close of next year, results will be obtained with direct coupling that will show it is possible to use a direct coupled motor even for so small work as street cars, that is quite as efficient, taking it all the way through, taking the total efficiency of the system, as gearing.

Mr. Leonard—With reference to the statement in my paper regarding the burning out of the telephone exchange, that statement was based on information I received from the telephone manager's office yesterday afternoon.

In regard to the difficulty and trouble experienced by the telephone exchange people, on account of the ground circuit of the electric railway, it has been largely, if not altogether remedied, by the erection of a metallic circuit, or what amounts to the same thing; running out a large copper wire to which the telephone wires are grounded instead of going to a gas pipe as

ordinarily. The difficulty has been obviated in that way; but there are quite a number of private telephone lines put up by various people, including our railway company, which cannot afford to go to the expense of putting up metallic circuits, and the result has been that we have been obliged to discard our private telephone line and pay tribute to the telephone company and their metallic circuit system.

With respect to the mechanical difficulties which Mr. Sprague alluded to, and which, of course, have been improved upon since the road was first erected, it is true that those mechanical difficulties can be considered as temporary and not inherent; but the electric road at Richmond was put forward as being a sample, I may say, of what has been accomplished, and of course we could only take what was actually being done, and criticised it accordingly. This I endeavored to do in the few remarks I made. That the work is susceptible of improvement is, of course, at once apparent to almost everyone; and that Mr. Sprague has in other cities succeeded in improving on the overhead system is nothing more than what would be expected from the ingenuity and skillfulness with which he has overcome the difficulties that were encountered in the Richmond enterprise.

Mr. Thomas Whiteside Rae (called upon by the chairman)—There is nothing that I have to say in addition to the remarks that have been given to-night, and I would like to record my hearty concurrence with Mr. Sprague's dictum respecting overhead lines. It is simply, as with most engineering questions, a financial rather than a technical one. One may have a good, durable, sightly overhead line by simply paying sufficient money for it. As at present constructed they do develop obstacles of various kinds and certainly are not as symmetrical as they might be, and do lack the perfection that might be given by the expenditure of more money. This question arises, though it is quite possible, I think, to make use of an underground conduit at perhaps no greater expense (certainly no greater when one considers the cost of maintenance of a properly built conduit), than a properly built overhead system would entail, and the difficulties which Mr. Leonard referred to, I think, cannot fail to be recognized by everybody; but that they are essentially inherent to the system does not necessarily follow, as Mr. Sprague has pointed out very clearly. The question is a financial one rather than a technical one.

Mr. Sprague—I think we will know much more about it when we have gone through a Northern winter which we shall do very soon. We have track-cleaning cars, and we shall put ample power behind them and can do the work of cleaning much faster than with horses because we have the power behind us rather than ahead of us.

Dr. S. S. Wheeler—Mr. Sprague in speaking of the liability of the wire to wear from the electricity mentioned the fact that it could not possibly wear because it was only in contact at one point at a very small part of the time—about a thousandth of the time. I should think that the fact of wear would be due to a very minute jump that the electricity would have to make when the roller hops a little off the wire. In fact, when he said that the roller was only in contact with any particular part of the wire about a thousandth of the time I thought he only referred to the danger of it hopping off.

Mr. Sprague—It was not that to which I referred. It is not the same as a sliding contact on the wire. Your wheel is turning all the while and there is no difference of potential between the part you leave and the part you are going on. You have a good contact where the trolley is held up by a good spring; you may inspect that wire by a microscope and detect very little signs of wear at all. There would be a very slight frictional wear, and it is probable there is a certain percentage of slip of these trolley wheels on the wire. I have, after eight months wear on the very heaviest portion of the line, very carefully inspected the wire, which was chemically cleaned, and I was agreeably surprised to see the small evidence of depreciation. If there is no sparking then the wear is entirely due to friction. The fact is the wear is remarkably light.

The Chairman—We would be very glad to hear from some member of the society, which has been our host here so long and allowed us to use its rooms. I believe Mr. Emery, of the Society of Civil Engineers, is present. He may have something to say to us.

Mr. Charles E. Emery (of the Society of Civil Engineers)—Gentlemen: This is a complete surprise. I came here to learn, because I know nothing of the subject; but I certainly am very much edified and I congratulate you, not only on the advance in electrical science, but on the advance you have made in organizing a society in which you can all join in the discussion of subjects which are so interesting to you and to us all, and I trust that you will grow to be one of the strongest and best societies in the country. Thanking you for the attention of calling on us I will ask to be excused.

Mr. Sprague—I would like to make one remark in regard to lightning. We had the line struck by lightning several times, and we have had motors on cars burnt out, but I believe I may safely say now that we have got lightning pretty well harnessed. I believe now there is no difficulty whatsoever in absolutely and perfectly guarding a car or a central station, so that lightning simply cannot get to the machine. We had three darkies sitting on the back dashboard of a car; one of them was sitting on the switch. The lightning came in, and grounded through the switch. Those three darkies jumped off the car at a very lively pace, but there was no danger. We have had the lightning come in and ground through the switch at the time the motor men were running the car. They paid not the slightest attention to it. They simply heard the click—that was the end of it. It will now be perfectly guarded against. It cannot get into our machines, and it cannot get into our stations; at least if it does it is only one time in 10,000, and then it goes to earth harmlessly.

Mr. T. Commerford Martin, chairman of the committee on papers and meetings, made the following announcement—The next meeting will be held on November 13th. The papers are as follows:—Professor W. E. Geyer, of the Stevens Institute, will read a paper on "A New Motor for Direct and Alternating Currents." We have with us this evening a gentleman whose acquaintance I think you will be glad to make. He is one of the leading electricians and mathematicians of France; he is also well known as one of the leading contributors to the leading electrical paper in France, *La Lumière Electrique*, Mr. Abdank Abakanowicz. I am very glad to announce that on the same evening, November 13, that gentleman will favor us with two papers, both of which will be accompanied by experiments and demonstrations; one will be on the Carpentier electrical method of recording and reproducing music; the other will be on the Abdank magnetic coil.

Adjournment.

ANNUAL REPORT

OF THE

PRESIDENT OF THE WESTERN UNION TELEGRAPH COMPANY.

FOR THE YEAR ENDED June 30, 1888.

CAPITAL STOCK.

The capital stock of the company outstanding is $86,199,852.06, of which $25,976.70 belongs to and is in the treasury of the company. It was increased during the year to the extent of $5,000,000 for the special purpose of acquiring the Baltimore and Ohio Telegraph Co. A small portion of it is still represented by certificates of indebtedness, for which capital stock certificates have not yet been issued.

BONDED DEBT.

The bonded debt at the close of the year was as follows:—

Bonds due March 1, 1900, 6 per cent	$871,398.00
Bonds due May 1, 1900, 7 per cent	4,920,000.00
Bonds due May 1, 1902, 7 per cent	1,325,000.00
	$7,116,398.00
Less balance of sinking funds appropriations not yet used for redemption of bonds	379,359.68
	$6,737,038.32

During the year Sterling bonds due March 1, 1900, to the amount of £4,100, and building bonds due May 1, 1902, to the amount of $11,000, were redemed by the sinking fund trustees.

BUSINESS OF THE YEAR.

Surplus, July 1, 1887		$7,002 185.11
The revenues, expenses and profits of the year ended June 30, 1888, were as follows:—		
Revenues	$19,711,164.12	
Expenses	14,640,592.18	
Profits		5,070,571.94
		$12,072,757.05
From which there was applied:—		
For dividends	$4,043,949.81	
" interest on bonds	490,258.30	
" sinking fund appropriations	40,000.00	
		4,574,208.11
Deducting which, leaves surplus, June 30, 1888, of		$7,498,548.94

The expenses for the year were:—	
For operating and general expenses	$10,065,843.27
" rentals of leased lines	1,942,485.80
" maintenance and reconstruction of lines	2,085,126.54
" taxes	355,877.74
" equipment of offices and wires	241,258.83
Total expenses as above	$14,640,592.18

RECAPITULATION.

The net profits for the year were		$5,070,571.94
Out of which there was paid:—		
For interest and sinking funds	$530,258.30	
Four quarterly dividends, aggregating	4,043,949.81	
And added to the surplus invested in new property	496,363.83	
Making		5,070,571.94
The increase in gross revenues over the previous year was		$2,519,254.17
In expenditures		1,485,923.64
And in net earnings		1,033,330.53

The maintenance and operation of 14,561 miles of additional line, with 91,607 miles of additional wire, and 1,583 additional offices, requiring 2,821 additional employés, and the transmission of 4,069,425 additional messages, made an increase of expenditure inevitable; but added to the necessary increase of maintenance and operation, there was the total expense of the Baltimore and Ohio system for some months, with the additional cost of buying off onerous contracts for leases of useless offices, and for other privileges and services which could not be utilized, the continued reconstruction of trans-continental lines, and the extraordinary expense of rebuilding and repairs consequent upon the memorable blizzard of last March.

CONSTRUCTION AND ACQUISITIONS.

In addition to the acquisition of the Baltimore and Ohio Telegraph system, consisting of 6,711 miles of lines, carrying 54,087 miles of wire, for which $5,000,000 were paid in the capital stock of the company at par; and of the New York and Southern Telegraph system of 1,528 miles of lines, and 5,090 miles of wire, there was constructed directly by the company and paid for out of the treasury 6,322 miles of line and 32,430 miles of wire, on which account there was appropriated $1,219,590.67 in cash.

There was also taken and paid for in cash $400,000 of additional stock in the Metropolitan Telegraph and Telephone Co. at par.

The total additions to the plant were 14,561 miles of lines and 91,607 miles of wire, and 1,583 additional and newly equipped offices. The acquisitions during the year in mileage of lines and wire and number of offices are about twice as great as the entire plant of any competing system the company ever had, and greater in mileage of wire than the entire system of this company after its consolidation with the American and United States Telegraph companies in 1866.

The average rate received per message during the year was 31¼ cents, as against 30⅜ cents for the previous year; and the average cost to the company of handling its messages was a fraction greater than the previous year, 23¼ cents, per message. The increase of less than one cent in the average rate collected is due partially to the advance of the 10 and 15 cent rates for short distance messages, but more largely to the greater percentage of increase in the long-distance messages, on which the rates have been reduced. In ascertaining these average rates it is necessary to eliminate from the gross revenues all that has not been received for the transmission of messages, and from the expenses all that does not pertain to such transmission.

GENERAL STATEMENT.

The following exhibit shows the revenues and disbursements of the company for 22 years from July 1, 1866:—

Surplus of income acc', July 1, 1866..	$275,357.24	
Net revenues for 22 years, from July 1, 1866, to June 30, 1888	91,108,369.59	
Making an aggregate, June 30, 1888, of		$91,383,726.83

During this period there was applied:—

For cash dividends	$51,185,565.07	
For scrip dividend	1,199,852.06	
For cost of 59,606½ shares of Western Union Telegraph stock, purchased and owned by the company, which was distributed to stockholders in 1879	3,302,198.90	
For cost of 72,010 shares of Atlantic and Pacific Telegraph stock, purchased and owned by the company, the proceeds of which, in Western Union stock, were distributed to stockholders in 1881	1,806,250.00	
For interest paid on company's bonds	9,173,597.19	
For cost of 396⅓ shares of Western Union stock, purchased and owned by the company, which were canceled to make the capital stock, after the issue of the new stock in 1881, exactly $80,000,000	26,836.00	
For amount reserved for interest on bonds and for sinking funds, accrued to June 30, but then not yet due and payable	106,086.64	$66,800,385.86
Leaving a surplus of		$24,583,340.97

Which is represented as follows:—

Construction of new lines, erection of additional wires, patents, etc., prior to October 1, 1881	$9,540,977.55	
Purchase of telegraph lines and of the stocks of companies leased by the Western Union Co. (upon which interest or dividends are paid as rental) prior to October 1, 1881	2,448,182.66	
Gold and Stock Telegraph Co.'s stock (18,905 shares)	1,176,009.00	
International Ocean Telegraph Co.'s stock (15,170 shares)	961,606.42	
Brooks' Underground Telegraph Co.'s stock (1,000 shares)	95,000.00	
Southern Bell Telephone and Telegraph Co.'s stock (1,687 shares)	84,825.00	
Sundry other stocks and bonds	88,157.33	
Western Union bonds redeemed and canceled	1,488,588.40	
Sinking fund (portion not yet used for redemption of bonds, exclusive of interest allowed by trustees)	311,917.69	
Broadway and Dey street building ... $2,365,689.52; Less amount provided from the proceeds of bonds issued ... 1,802,202.00	563,487.52	
Real estate, other than above	144,300.38	
Supplies and material on hand unissued	182,290.06	
Surplus, June 30, 1888	7,498,548.94	
		$24,583,340.97
On account of these assets, a stock distribution was made in 1881 to the amount of		15,526,590.00
Deducting which leaves a balance of.		$9,056,750.97

The above balance of $9,056,751, is the aggregate surplus not represented by any form of capitalization, and which has chiefly been invested in construction and new properties. The difference between this balance and that which is shown in the statement of "business for the year" is because of appropriations for construction out of earnings previous to October 1, 1881, over and above the $15,526,590 capitalized by the issue of capital stock in 1881, and which, previous to October of that year, had been carried into the quarterly statements. Since that period, in compliance with a resolution of the board of directors, a separate account of construction and purchase of new properties has been kept, which, as shown in the last previous report, has been credited with $1,000,000 received from the sale of bonds; with $143,976.87 from the sale of telephone properties; and with $1,199,852.06 capitalized by the issue of scrip dividend since converted into stock—all of which were applied as a credit to this account.

Of the $51,185,565.07, which has been paid to stockholders in cash dividends since July 1866, $30,051,632.73 have been paid since the consolidation with the American Union and Atlantic and Pacific companies in January, 1881, and in addition thereto $12,198,823.83 have been advanced and paid within the same period for new and additional properties, on account of which, however, $1,143,976.87 has been derived, as before stated, and the remainder advanced and paid in cash out of the treasury of the company. A fraction less than $1,200,000 was capitalized by the issue of the scrip dividend, and credited to this account.

STATISTICS.

The following table exhibits the mileage of lines operated, number of offices, number of messages sent, receipts, expenses, profits and average tolls and costs per message for each year since 1866.

Year	Miles of poles and cables.	Miles of wire.	Offices.	Messages.	Receipts.	Expenses.	Profits.	Average tolls per message.	Average cost to company of message.
1866	37,380	75,686	2,250	....	$	$	$		
1867	46,270	85,291	2,565	5,879,282	6,568,925.36	3,944,005.63	2,624,919.73	.....	....
1868	50,183	97,594	3,219	6,404,595	7,004,560.19	4,362,849.32	2,641,710.87	104.7	63.4
1869	52,099	104,584	3,607	7,934,933	7,316,918.30	4,568,116.85	2,748,801.45	89.3	54.2
1870	54,109	112,191	3,972	9,157,646	7,138,737.96	4,910,772.42	2,227,965.54	75.5	51.2
1871	56,032	121,151	4,606	10,646,077	7,637,448.85	5,104,787.19	2,532,661.66	69.5	45.7
1872	62,033	137,190	5,237	12,444,499	8,457,095.77	5,666,863.16	2,790,232.61	66.2	43.8
1873	65,757	154,472	5,740	14,456,832	9,333,018.51	6,575,055.82	2,757,962.69	62.5	43.4
1874	71,585	175,735	6,188	16,329,256	9,262,653.98	6,755,733.83	2,506,920.15	54.9	39.5
1875	72,833	179,496	6,565	17,153,710	9,564,574.60	6,335,414 77	3,229,157.83	54.	35.2
1876	73,532	183,832	7,072	18,729,567	10,034,983.66	6,635,473.69	3,399,509.97	50.9	33.5
1877	76,955	194,323	7,500	21,158,941	9,812,352.61	6,672,224.94	3,140,127.67	43.6	29.8
1878	81,002	206,202	8,014	23,918,894	9,861,355.23	6,309,812.53	3,551,542.70	38.9	25.
1879	82,987	211,566	8,534	25,070,106	10,960,640.46	6,160,200.37	4,800,440.09	38.6	25.2
1880	85,645	233,534	9,077	29,215,509	12,782,894.53	6,948,956.74	5,833,937.79	38.5	25.4
1881	110,340	327,171	10,737	32,500,000	14,393,543.85	8,485,264.13	5,908,279.72	38.4	25.6
1882	131,060	374,368	12,068	38,842,247	17,114,165.92	9,996,095.92	7,118,070.00	38.2	25.8
1883	144,294	432,726	12,917	41,181,177	19,454,902.98	11,794,553.40	7,660,349.58	38.	26.
1884	145,037	450,571	13,761	42,076,226	19,632,939.60	13,022,503.90	6,610,435.70	36.5	25.2
1885	147,500	462,283	14,184	42,096,583	17,706,833.71	12,005,909.58	5,700,924.13	32.1	24.9
1886	151,832	489,607	15,142	43,289,807	16,298,638.55	12,378,783.42	3,919,855.13	31.8	23.4
1887	156,814	524,641	15,658	47,394,530	17,191,909.95	13,154,628.54	4,037,281.41	30.4	23.
1888	171,375	616,248	17,241	51,463,955	19,711,164.12	14,640,592.18	5,070,571.94	31.2	23.2

The foregoing table exhibits the growth and increase of the property and business of the company year by year for 22 years. The additions to the property have already been stated. The traffic shows an increase of over 4,000,000 messages handled, and of 20 per cent. in the revenues derived from the hire of leased wires mainly to the press and to business houses, the messages over which are not taken into the count The increase in gross revenues was over 2,500,000, and over 1,000,000 in net profits, as compared with the business of the previous year.

Attention is called to the last two columns of the table, showing the steady reduction in rates of tolls and in the cost of the service for 20 years. It will be seen that the public are enjoying a superior service at less than half the average rate of tolls that it cost the company to perform the service 20 years ago.

PRESS SERVICE.

The service for the press, and the aggregate revenues therefrom, continue to bear about the same proportion to the general traffic in the transmission of messages, although there was an increase of 50 per cent. in the amount received for the lease of wires to the various press associations and individual papers now aggregating over 12,500 miles of wire leased exclusively for press reports. On these wires they employ their own operators, and the reports transmitted do not enter into the accounts of the company, yet the associated press service handled by the company shows a small increase in the number of words transmitted, whilst the special press service (being reports sent to a single newspaper), shows an increase of 32 per cent.; and the total revenues for account of press service, including the rental of leased wires, show an increase of 28 per cent. over the previous year.

The table appended exhibits the assets in the treasury, the only material changes from last year being the addition of 4,000 shares of the capital stock of the Metropolitan Telegraph and Telephone Co., and the addition of $150,000 each in the capital stocks of the American District Telegraph companies of Baltimore and of New York.

The ensuing year, of which the results of the first quarter are approximately known, promises a greater increase of traffic than ever before realized, and the outlay for new property is not likely to be nearly so great. Respectfully submitted,

NORVIN GREEN, *President*.

THE NEW YORK BOARD OF ELECTRICAL CONTROL.

The meeting of the Board of Electrical Control, on the 17th inst., was chiefly remarkable for the exhibition of the determination of the board to expedite the satisfactory solution of the subway question, not only by the active measures that have lately been carried out, but by inviting the participation of the electrical companies in a discussion of the situation.

A letter addressed by the commissioners to the United States Illuminating Co., the Brush Electric Co., the East River Electric Light Co., the Harlem Lighting Co., the American Electric Manufacturing Co., the Mount Morris Electric Light Co., the North New York Lighting Co., the Ball Electric Illuminating Co., and the Daft Electric Power Co., invited those companies to attend a meeting of the board on Friday, the 19th inst., for the consideration of the subway question. The letter refers to the opposition which has been met with on the part of corporations engaged in the electric lighting business to the burial of their wires, and the lack of co-operation which has characterized the position assumed by certain officials, and goes on to show that under existing conditions it is impossible for the board to carry on its work in the manner that it evidently intends. Reconstruction is insisted on, and it is stated that the rules and regulations drawn up by Dr. Wheeler will be submitted to the attention of the meeting on Friday, 9th. "It is the opinion of the committee appointed to report on the matter, and the board, that under proper regulations the use of electric conductors for high tension currents can be made reasonably safe, and it is believed that the welfare of the corporations demands this co-operation." The letter indicates the possibility of considerable concessions being made to the electric lighting companies, but at the same time it is not difficult to trace the hand of iron under the glove of velvet.

Dr. Wheeler's report showed that 283 notices of violations of the rules and regulations of the board had been sent to the Bureau of Incumbrances. Of these 183 related to dead wires, none of which had been acted upon. One hundred related to dead poles, of which 40 had been acted upon, 60 remaining unattended to. The latter comprise all the notices but 13 of dead poles and dead wires belonging to the United States Illuminating Co., and about 33 miscellaneous notices. No dead wires have been removed by the Bureau of Incumbrances, excepting in the few cases to clear lines and poles which were to be taken down, the superintendent of the bureau stating that he has no force of men with which to do this work. The work of removing the dead poles has been carried on continuously from the time it was started until Oct. 15. The forty notices which have been acted upon by the Department of Public Works have entailed the removal of 312 dead poles and 404,183 feet of dead wire. There have been 214 new notices of violations of rules and regulations since the last meeting of the board. Dr. Wheeler also gave a full list of the lines of wires, in accordance with the direction of the board.

A letter from Mr. W. H. Eckert, general manager of the Metropolitan Telephone Co., reported very satisfactory progress in the removal of wires, and Commissioner Gibbens commended the way in which the company were pushing the work, and stated that they had removed 15,000 miles of wire at a considerable cost. They had spent in the lower part of the city $1,000,000 to get everything in good form.

Secretary Moss reported that the wires in Second avenue between Sixty-fourth and One Hundred and Twentieth streets have been removed, and that Sixth avenue is clear of poles from Twenty-first to Forty-eighth street.

The Western Union Co. stated that arrangements to remove the wires in Broadway between Fourteenth and Thirty-fourth streets are being made with a view to their being placed underground. The telephone company is preparing to bury the wires in this section.

The bad condition of the conduits in Park Row and lower Broadway was discussed, and a report submitted showing that, owing to leaks from the New York Steam Heating Co.'s pipes the temperature in the conduit man-holes at some points is as high as 209 degrees. The Western Union Co. reported its cables as so injured as to necessitate their replacement, and ask permission to distribute five 50-conductor overhead cables from the main office to the branches.

Chief Engineer Beckwith, of the Construction Company, stated that the work on the subways would probably be continued until Dec. 1, the same as last year. Up to the present time about 40 miles of trench have been dug, 500 miles of single ducts have been laid, and 550 man-holes have been constructed.

The business of the board is just now so urgent that until further notice the commissioners will meet Tuesdays and Fridays at 12 o'clock.

A special meeting of the board was held at the office of the board on Friday, the 19th inst., at 11 o'clock.

Further time was given for the report of the engineer and expert on the question of overcoming the difficulty of the steam pipes, in order that additional investigations could be made. The rules and regulations which have been prepared by Dr. Wheeler were submitted, and eventually adopted as far as rule 29, when their consideration was postponed in order to allow Mr. E. Lauterbach to read a letter from the chief engineer of the Construction company, giving temperature tests on lower Broadway. These showed that the majority of the man-holes had a temperature of 80 to 100 degrees, notably at Park Row, Cedar street and Exchange place. The experiments that had been carried out showed conclusively that the heat was not caused by radiation, but by the leakage of the steam pipes. The company had shown the greatest willingness to meet the necessity for repairs; but it was a question whether any preventive known to science would actually overcome the difficulty. This raised the question whether a private corporation like the Steam Heating Co. should be allowed to use the streets in any way which would interfere with the convenience and comfort of the public.

Mr. Andrews, the president of the Steam Heating Co., said that the company had constructed this plant with the best materials that could be got, and had instructed their engineers to put in the best work that could be done. The usual factor of safety was five to one, but they had doubled this and made it 10 to one. They run their steam at a pressure of 85 pounds through pipes that could stand a pressure of 1,000 pounds, so the fault could not lie in any general weakness or ineffectiveness. The fault was due to one single blunder of their engineer, in using wooden wedges for holding the pipes together, instead of cast-iron wedges. The wooden wedges shrank with heat and age, and left the joints of the pipes open. To put in iron wedges on the two miles of pipes originally would have cost $100, but in repairing or substituting they had already spent $250,000. That this was the sole cause of the difficulty was proved by the fact that their pipes uptown, *i. e.*, in 58th street, which are put together with iron wedges, have never shown a particle of leakage. After this somewhat startling admission, on motion of Commissioner Gibbens, it was resolved to defer further consideration of the subject until the expert and engineer of the board had been heard from.

Commissioner Gibbens, as a committee to consider the petitions of the Manhattan Electric Light Co. and the Safety Electric Power Co. for the privilege of running wires and doing electrical business in New York, said that the papers seemed to be in due form, and, on motion, the petitions were granted.

A communication was then read from the Bureau of Incumbrances, enclosing a letter of the United States company, which stated that certain enumerated poles and wires were not dead, as reported to the board, and Superintendent Richardson asked to have them verified. The report of the expert was read, stating that they had been re-inspected and all found to be dead, excepting one or two cases where the poles or dead wires had been put into use recently by putting up the connections with new pieces of wire, and so connecting the fixtures complained of on to line

circuits. The secretary of the board was directed to write to Mr. Richardson stating these facts, and repeating that the wires and fixtures were all dead, according to the meaning of the law, those that are now alive having been connected recently.

An application presented from the United States company for permits to connect a number of lamps, etc., was granted. A permit was also applied for by the same company to make numerous repairs, to which the secretary was directed to reply that according to the rules and regulations of the board, permits for repairs were not needed, except in the condemned district, where permits will not be granted.

A permit was granted to the East River company to run wires on 6th avenue and 18th and 38th streets. The meeting then adjourned.

At the meeting of the board on October 30, a number of permits were granted to connect lamps with existing circuits. The mayor referred to the board a letter from John A. Gano in relation to safety cut-outs, which was referred to the expert of the board. The request of the Western Union Telegraph Co. for permission to string five cables on poles was laid over until Friday next. The Western Union Telegraph Co. allege that the extreme heat in the subways destroys their cables. The telephone company also claim that their wires are badly damaged by the heat.

POINTERS.

.... I HAVE often been asked the question whether alternating dynamos can be worked in parallel. They can, when they are fully loaded, down almost to half load, but below that they do not synchronize.—*Professor George Forbes.*

.... FIRE, water, earth, and air have long been his slaves, but it is only within the last few years that man has won the battle lost by the giants of old, has snatched the thunderbolt from Jove himself and enslaved the all-pervading ether.—*G. F. Fitzgerald.*

.... ALL attempts to revive the Franklinian, or material theory of electricity, have to be so loaded with assumptions, and so weighted with contradictions, that they completely fail to remove electricity from the region of the mysterious.—*W. H. Preece.*

.... TO make important progress, it is necessary to leave the beaten track traveled over again and again by the scientific schools, and to seek some elevated standpoint from the outside where we can look down upon matter and its associated forces as a whole.—*S. Alfred Varley.*

.... THE extreme flexibility and capacity for self-regulation possessed by any properly organized system of alternate current generation, distribution and re-conversion, renders the alternating current peculiarly applicable to the varied requirements of electric railway transit, and will beyond doubt contribute materially to an early introduction and subsequent extension of this as yet untried system of electric railway operation.—*Elias E. Ries.*

.... ALTHOUGH it is a sad confession to have to make, that the very best of our steam engines only utilizes about one-sixth of the work which resides (if the term may be used) in the fuel that is consumed, it is, nevertheless, a satisfaction to know that great economical progress has been made, and that the 6 or 7 pounds of fuel per horse-power hour consumed by the very best engines of Watt's days, when working with the aid of condensation, is now brought down to about one-fourth of this consumption.—*Sir Frederick Bramwell.*

MISCELLANEOUS ITEMS.

The *New York Herald*, of the 11th, contained the details of a plan—said to have originated with five Western Union operators—for tapping the wires leading to the Jerome Park race course, and so securing the results of the races in advance. Although the details were said to have been carefully worked out and the apparatus in position, the scheme failed on account of a too sensitive conscience on the part of one of the plotters. The Western Union officials deny the truth of the story.

There is very little of interest to electricians at the American Institute fair, the fifty-seventh opening of which took place on October 3d. Mayor Hewitt delivered one of his characteristic addresses on the occasion.

On October 5th, at the trial of the long drawn out Snow-Alley case, a verdict was found in favor of Snow, at the town of Dedham, Mass. Judge Blodgett presided, and the depositions of Lester A. Bartlett, Thomas Wallace, Elisha Gray, and others, were read; and George L. Shorey, and Hon. Alanson W. Beard, appeared as witnesses. Mr. Beard, as president of the Postal Telegraph Co., testified as to what he knew of Mr. Snow's former relations with Mr. Alley. Mr. Snow testified in rebuttal. The case was then given to the jury and a verdict rendered. Exceptions were taken, however, and as far as is known, the case is still on its travels through the courts.

The electrical committee of Philadelphia city councils have agreed to report for passage the ordinances authorizing the American Telegraph and Telephone Co. to lay conduits on the west side of Fifty-second street to Lancaster avenue. Similar disposition was made of a bill empowering the Bell Telephone Co. to extend its conduits on Third street from Vine to Callowhill, thence on Callowhill to St. John, to the centre of the square between Callowhill and Noble, and also on South street from Second to Front, and on Walnut from Water street to the Delaware river.

A bitter fight came to a close recently when the Fort Wayne-Jenney company received the contract for lighting the city of Bloomington, Ill. Three years ago the Thomson-Houston company, of Chicago, installed a plant in the city on the understanding that the municipality should have the option of purchasing it. There was determined opposition to the purchase of the Thomson-Houston plant, and the Fort Wayne Jenney decided to compete for the sale to the city of a complete outfit. The struggle became at once acrimonious; charges and counter-charges were so numerous that the citizens became intensely interested in the contest, and two factions were formed. Representatives of each company were honored by receptions by their respective partisans. Old friends quarreled about the relative merits of the two companies, and the fight became decidedly unique. The Fort Wayne Jenney obtained a majority in the council, and secured the contract at a bid of $70,000. Two hundred and forty lights will be supplied with current by eight dynamos. The lights will be suspended from mast arms.

Mention was made last month of the effort of several unfortunate stockholders of the defunct Great Western Telegraph Co. to escape the disagreeable duty of paying assessments on their holdings. Recently, another bill in chancery was filed by Senator Farwell and others, asking that a full accounting of the affairs of the company be had, in order that the rights of stockholders might be determined.

ELECTRIC LIGHT AND POWER.

THE HEISLER incandescent light system has been in operation over a year at Ogden, Utah, where its claims for long-distance transmission are put to the test of a distance of six miles from the water power station to the city. Very favorable reports of its success are made by Mr. David F. Walker, president of the Ogden Electric Light Co., including a gratifying statement on that most interesting point to investors—viz., the financial result. Mr. Walker says the plant has been "a financial success from the start."

PROVIDENCE, R. I.—The new station (now under construction) of the Narragansett Electric Lighting Co., of Providence, R. I., is carefully described and illustrated by the Providence *Sunday Journal*, of October 21st. The engines will be triple expansion, of 1,000 and 500 h. p., with steam jacketed cylinders and receivers. The Reynold's engines built by E. P. Allis & Co., of Milwaukee, have been selected. Mr. Reynold's has guaranteed an indicated horse-power on 12½ pounds of water per hour, which is said to be the lowest guarantee on which an engine was ever built. The engines will have cylinders 13-18-30 inches in diameter with 48 inches stroke. The fly-wheel will be 16 feet running at 100 turns per minute. The length of the boiler house will be 200 feet, with 12 batteries of boilers, and the entire lot will develop with the engines to be used, more than 10,000 h. p. The station will be equipped with the Thomson-Houston system for arc lighting and electric power, and the Westinghouse system for incandescent lighting.

THE WESTINGHOUSE ELECTRIC CO. have issued the most sumptious circular that we remember to have seen. As regards paper, letter-press, illustrations and binding, it is nothing less than lavish in its richness and elegance. Collectors of the unusual in any branch of publication who are fortunate enough to get possession of a copy will be quite sure to give it a place on their shelves as an example of the luxury to which business publications have attained. The circular is a large one—17 by 12 inches—and is bound in a heavy bronzed paper by copper rivets at the back, and heavily embossed in striking but chaste designs. In 63 pages—profusely and beautifully illustrated—are to be found descriptions of the lighting and motive power alternate current apparatus of the Westinghouse Electric Co.

THE EDISON ELECTRIC LIGHT COMPANY'S new pamphlet-circular exhibits a list of 169 central stations (in operation or under contract) employing the Edison system, with an aggregate of 391,305 lamps. The substantial character of the investments making now-a-days in the business of electric lighting is indicated in the buildings erected for central stations. The Edison circular includes among its illustrations well executed cuts of the station buildings at 26th street, New York; at Detroit, Mich.; at Philadelphia, and at Chicago, all being houses of an obviously superior and solid kind, befitting the location of established business enterprises. Interior views of several stations are also given.

A RECORD is kept of the life of the incandescent electric lamps used in the service of city lighting companies, and one lamp, a 20 c. p. Sawyer-Man, taken from the *Journal* counting room last week, showed a life of 5,000 hours, an exceptionally good record. Another recently taken off had 4,000 hours service to its credit.—(Providence, R. I.) *Sunday Journal.*

THE WESTINGHOUSE ELECTRIC CO. have contracted to furnish a plant of 25,000 lamps, Westinghouse alternate current system, to the Metropolitan Electric Supply Co., Limited, London.

THE HILL CLUTCH WORKS, of Cleveland, Ohio, have made a very successful move in the right direction, in undertaking the design and construction of power plants complete for electric lighting, including the designing and erection of station buildings. It has become a trite remark in electric light circles that illy considered power stations have been the bane of the business. As engineers and contractors, the Hill Clutch Works undertake station buildings and the complete line of power transmission machinery—in fact the entire light station with the exception of the electrical outfit. This method secures unity of plan throughout, and a single responsibility for the complete power station, and can hardly fail to be advantageous practically and economically. The large Brush plant at Minneapolis, was put in by the Hill Clutch Works a year ago, and they are now engaged upon the plant at St. Paul, which is nearing completion. This station is to have 2,500 h. p. of engine capacity, running 40 dynamos.

THE Westinghouse Electric Company have added 52 stations to their list since December last. Below is a list of them. This list comprises central stations only and does not include any isolated lighting plant.

LIST OF CENTRAL STATIONS, WESTINGHOUSE ALTERNATE CURRENT SYSTEM, ERECTED OR CONTRACTED FOR FROM DECEMBER, 1887, TO OCTOBER 15, 1888.

MANUFACTURING AND TRADE NOTES.

MR. J. H. SHAY, of the Charles Munson Belting Co., has secured the contract for the belt equipment of the Brush Electric Light Co., of Baltimore, Md.

MR. CHARLES FELSING, analytical chemist, formerly with A. Merck, Darmstadt, Germany, has formed a business partnership with Mr. Chas. Reinmann, the glass-blower, for the manufacture of experimental apparatus.

MESSRS. JAS. W. QUEEN & CO., Philadelphia, send us their priced and illustrated catalogue of chemical apparatus. It makes a volume of no less than 364 pages, including a carefully prepared index. A list of chemical books is also included. The catalogue of apparatus and supplies is extremely comprehensive, while the illustrations and descriptive matter are well adapted for the information of students or others engaged in chemical work.

THE ROBERTSON LEAD ENCASING WORKS, 131 Water street, Brooklyn, N. Y., have patented a device for covering cables with a lead shield of any thickness while the insulating compound is being put on. They have made cables for several telephone companies, and their device is in use by a number of the large wire manufacturers.

THE WOODWARD ELECTRICAL CO., of Detroit, Mich., under the management of Mr. F. B. Trout, has done much to popularize the storage battery for central station installations. Their board of directors comprise a number of Michigan's most substantial business men.

THE "LAW BATTERY" in its latest form as supplied by the Law Telephone Co., 112 Liberty street, New York, exhibits several points of interest, particularly respecting the matter of durability. The negative element is a double cylinder. Both elements are secured beneath the glass cover, instead of passing through the cover in the usual manner. The cover, of blue glass, is tightly fitted, to prevent evaporation of water and creeping of salts.

PERFORATED LEATHER BELTING.—A novel method of preventing "air cushions" in belts run at a higher rate of speed, was patented by Messrs. Chas. A. Schieren & Co., of New York, May 24, 1888. Perforations are made through the belts in a regular and uniform manner, and at equal distances apart, over the entire surface, thus insuring equal tension and leaving the tensile strength of the belt uninjured. Besides preventing "air cushions" these belts are said to run smoother, steadier, and make less noise, than ordinary belts. They are well adapted to high speed dynamos, in which class are included those of the alternating current system.

AT THE CENTENNIAL EXPOSITION of the Ohio Valley, in Cincinnati, the Waterhouse Electric and Manufacturing Co. were awarded a gold medal and two silver medals on their arc light plant exhibited. The judges accord the system high praise, and the Waterhouse company are to be congratulated on receiving their second gold medal, the first having been awarded at the Mechanics' Fair, Boston, in December last.

THE C. & C. ELECTRIC MOTOR CO. invited a number of gentlemen to St. Paul's chapel on the afternoon of October 23, to examine the application of one of their motors to the blowing machinery of the chapel organ. Those who attended were much pleased by the successful performance of the C. & C. motor. The action of the motor is easily controlled automatically from the bellows.

MR. C. J. HIRLIMEN, so long identified with the manufacture of Leclanché batteries in this country, has begun the manufacture of a cell of his own design, for which several improvements are claimed. The company is known as the Improved Patent Porous Battery Co., limited, 89½ Greene street, New York city.

THE WESTINGHOUSE ELECTRIC CO. announces its lease of the Consolidated Electric Light Co. and the Sawyer-Man Electric companies, its intention being to conduct the business of those two companies hereafter.

The Westinghouse company has heretofore been a large stockholder in the Consolidated company, but under the new arrangement, will control absolutely the lamp trade under the Sawyer-Man patents, and can thus manage it in the interest of an extension of its business in dynamos and incandescent lighting apparatus, which is already one of the most important in the world. The combined lamp factories of the company will now have a capacity of 7,500 lamps daily, and by means of an improved process lately acquired, lamps will be produced which, it is claimed, will give a larger amount of light from a given expenditure of power than any company has heretofore guaranteed. It is expected that the improved method of manufacture will inure to the benefit of consumers in a considerable reduction in prices.

It is said that the terms of the lease are such as to secure to the stockholders of the Consolidated company a substantial dividend, thus placing the stock of that company on a paying basis.

THE EMPIRE CITY ELECTRIC CO., 15 Dey street, New York, manufacturers and dealers in electrical supplies, issues an illustrated list of domestic and other signal apparatus, bells, push buttons, etc. They make a point of the Empire City disque battery.

ELECTRIC STREET RAILWAYS IN AMERICA.

Now in Operation.

ABBREVIATIONS.—**mi.**, miles of single track; **g.**, gauge; **lb.**, pounds rail per yard; **m.**, electric motors; **c.**, cars; **m. c.**, motor-cars; **h. p.**, horse-power; **T.**, T-rail. Name of electric system used is in SMALL CAPITALS.

Wichita, Kas.—Riverside & Suburban Ry. Co.—*Pr.*, G. C. Strong; *Supt.*, O. J. Chapman; (contract for 2 miles); 7 mi.; 30-40 lb.; 3 m. c.; overhead cond. THOMSON-HOUSTON.

Worcester, Mass.—Worc. & Shrewsbury—(To be changed from steam to electricity); 2.7 mi.; g. 3; overhead cond. DAFT.

RECAPITULATION.

Roads Now in Operation,	49
Roads Constructing or Under Contract,	49

Notes.

THE SOUTH ORANGE HORSE RAILROAD CO. is about to conclude arrangements with the Daft Electric Motor Co., to make a trial of the Daft electric railway system on the road between the stables and South Orange, provided the citizens along the line and the South Orange township committee give sanction to the erection of the poles and wires. The poles will be of octagonal yellow pine, painted and set in cement along the curb line on one side of the road, 100 feet apart, and each pole will carry an ornamental wrought-iron bracket from which the wires will depend. If the line is in every way satisfactory, endeavor will be made to get permission to continue it down through the city to the eastern end of the road.

THE THOMSON-HOUSTON ELECTRIC CO., since it took over the railway business of the Van Depoele company and entering into the construction and supply of street railway plant, have found it necessary to make a large increase in their manufacturing facilities in order to keep abreast with the remarkable growth in that branch of electrical work during the past year. The magnitude of the railway business has greatly exceeded their expectations.

THE SEATTLE, W. T. ELECTRIC RAILWAY AND POWER CO., of Seattle, Wash. Terr. was incorporated October 9th, by Frank H. Osgood, Edward C. Kilbourne, Thomas Burke, L. H. Griffith, G. M. Haller, Angus Mackintosh, and Victor H. Smith. This company was formed by the consolidation of the Seattle Street Railway Co. and the Electric Motor Co., for which Dr. Kilbourne recently obtained a franchise. It is now stated that the electric railway will be built at once. The capital stock of the new company is $120,000.

NEW YORK CITY.—The electric road of the North and East River Co.—Bentley-Knight system—is likely to be completed and in operation very shortly. Our readers will remember that work was suspended on this road nearly a year ago because of the opposition of the Bleecker Street Co. to the use of Fulton street by the electric company. An agreement between the companies is reported to have been reached, and it is expected that electric cars will be running by December 1st, connecting Fulton Ferry on the East river with the down-town North river ferries by way of Fulton street.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From September 25 to October 16, 1888.(inclusive).

Alarms and Signals:—*Hotel Signaling System*, A. Barrett and J. Zentner, 390,833. *Electric Bell-Pull*, P. A. Harris, 390,778, October 9. *Signaling Device*, J. Sax, 391,276, October 16.

Clocks:—*Apparatus for Synchronizing Clocks*, C. E. Hoefling, 390,230, October 2.

Conductors, Insulators, Supports and Systems:—*Electrical Conductor and Insulating Conduit*, R. F. Silliman, 389,948. *Elevated Frame-Work and Support for Electric Wires and Street Railways*, L. W. Brown, 390,001, September 25. *Device for Protecting Electric Conductors*, E. G. Acheson, 390,196, October 2. *Insulator or Bracket-Support for Electric Wires*, T. E. Adams, 390,741, October 9.

Distribution:—*System for the Distribution of Electric Energy*, G. and A. Pfannkuche, 389,974, September 25. *System of Electrical Distribution*, N. Tesla, 390,413. *Distribution and Control of Electricity for Lighting*, H. Edmunds, 390,463, October 2. *Coupling Dynamo-Electric Machines for Electric Distribution*, O. B. Shallenberger, 390,910. *Regulator for Electric Translating Devices*, same, 390,911. *Apparatus for Synchronizing Alternate-Current Dynamo-Electric Machines*, same, 390,912. *Synchronizing Electric Generators*, G. Westinghouse, Jr., 390,980. *System of Electrical Distribution*, O. B. Shallenberger, 390,990, October 9.

Dynamos and Motors:—*Electric Motor*, P. Diehl, 389,876. *Dynamo-Armature*, W. G. Meyers and F. E. Coward, 389,894. *Dynamo-Electric Machine*, W. Mather and E. and J. Hopkinson, 390,180, September 25. *Armature-Core for Dynamos*, W. S. Hill, 390,301. *Alternate-Current Dynamo*, E. Thomson, 390,318. *Dynamo-Electric Machine*, N. Tesla, 390,414. *Dynamo-Electric Machine or Motor*, same, 390,415. *Dynamo-Electric Machine*, C. S. Bradley, 390,439, October 2. *Dynamo-Electric Machine*, N. Tesla, 390,721. *Regulator for Alternate-Current Motors*, same, 390,820. *Electro-Dynamic Motor*, E. E. Ries, 390,904 and 390,905. *Multiple-Current Electric Generator*, same, 390,906. *Carbon Contact or Commutator Brush*, C. J. Van Depoele, 390,921. *Dynamo-Electric Machine*, J. Emmner, Jr., 390,955, October 9. *Dynamo-Electric Machine*, M. W. Parrish and W. R. Cole, 391,070. *Safety Attachment for Electric Motors*, C. F. Brush, 391,114. *Hand Magneto-Electric Machine*, J. B. Blair, 391,224. *Dynamo-Electric Generator*, G. and A. Pfannkuche, 391,270. *Regulation of Electric Motors*, L. S. Harris, 391,319, October 16.

Galvanic Batteries:—*Porous Cup for Galvanic Batteries*, E. M. Hewett, 390,597, October 2. *Galvanic Battery*, D. Humphreys, 390,674, 390,675, 390,676, and 390,677. *Battery Electrode*, H. J. Brewer, 390,748, October 9.

Lamps and Appurtenances:—*Electric Incandescent Lamp and Attachments*, I. W. Heysinger, 389,883, September 25. *Electric Arc Lamp*, R. H. Mather, 390,245. *Storm-Protector for Electric Lamps*, T. H. Brady, 390,440. *Process of Making Carbon Filaments*, T. A. Edison, 390,462. *Electric Light Circuit Cut-Off Switch*, W. A. Johnson, 390,481, October 2. *Globe for Electric Arc Lamps*, W. W. Downing, 390,846. *Incandescent Electric Lamp*, A. L. Reinmann, 390,903, October 9.

Measurement:—*Registering-Meter for Electric Currents*, J. D. Bishop, 389,870. *Galvanometer*, I. W. Chisholm, 390,067, September 25. *Electric Meter*, H. Bentz, 391,010, October 16.

Medical and Surgical:—*Galvanic Abdominal Truss*, L. Epple, 390,354. *Therapeutic Electrode*, J. H. Woodward, 390,544, October 2. *Galvanic Belt*, E. D. Granger, 391,364, October 16.

Metallurgical:—*Stack Furnace for Reducing Ores*, A. T. Hay, 390,964, October 9. *Device for Refining Metallic Ores*, H. H. Eames, 391,034, October 16.

Miscellaneous:—*Electric Testing Device for Card-Flats*, E. Tweedale, 390,101. *Electric Testing Device for Carding Machines*, J. Bullough, 390,113. *Electric Current Indicator*, P. B. Delany, 390,115, September 25. *Magnetic Cleaning Apparatus*, A. Hempel, 390,229. *Electrical Testing Apparatus*, J. W. Packard, 390,310. *Electric Circuit-Controller*, A. F. L. Willatowsky, 390,329, October 2. *Electrically-Operative Lock*, G. S. New, 390,795. *Electrical Stop Mechanism for Knitting Machines*, A. M. Newlands, 390,891. *Apparatus for Automatically Regulating the Flow and Temperature of Fluids*, G. A. Gustin, 390,960, October 9. *Electrical Switch*, J. S. Adams, 391,351, October 16.

Railways and Appliances:—*Railway Alarm*, A. G. Ingraham, 390,081, September 25. *Apparatus for Removing Ice from Railway-Tracks*, E. E. Ries, 390,619, October 2. *Electric Railway System*, D. G. Weems, 391,391, October 16.

Storage Batteries:—*Secondary Battery*, C. A. Faure, 389,882. *Electric Storage System*, W. H. McDonald, 389,935, September 25. *System of Utilizing Secondary Batteries*, H. Edmunds, 390,464, October 2. *Separator for Electric Batteries*, H. W. Butler, 391,229, October 16.

Telegraphs:—*Telegraphy*, S. D. Field, 389,888. *Telephonic, Telegraphic and Signaling Circuit*, E. I. Bernheim, 390,058, September 28. *Mechanical Telegraph*, J. B. Bennett, 390,642. *Telegraphy*, F. J. Patten, 390,802, October 9.

Telephones, Systems and Appliances:—*Telephone*, P. Wright, 390,428. *Telephonic Transmitting-Instrument*, R. D'Unger, 390,575, October 2. *Telephone Transmitter*, W. H. Collins, 391,356, October 16.

THE

ELECTRICAL ENGINEER.

Conducted by F. L. POPE AND G. M. PHELPS.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, *11 Wall Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. VII. NEW YORK, DECEMBER, 1888. No. 84.

SPECIAL NOTICE.—To afford an opportunity to become acquainted with THE ELECTRICAL ENGINEER, *the publishers will send it to any new address for* THREE MONTHS *for* FIFTY CENTS.

By arrangement with the publishers of the ELECTRICAL WORLD, *New York, and the* WESTERN ELECTRICIAN, *Chicago, the publishers of this journal are enabled to offer either of those weekly papers together with the* ELECTRICAL ENGINEER, *for* $5.00 *per year or the three journals for* $7.50. *To those of our present subscribers who so desire, we will supply either the* ELECTRICAL WORLD, *or the* WESTERN ELECTRICIAN, *one year for* $2.50, *or both for* $5.00.

WITH OUR ROAST TURKEY.

MAY not electricians join heartily in the grateful felicitations of the good old New England holiday this year? Benefits resulting chiefly from persistent and well-directed toil by the recipients far outrank all bounties as cause for gratitude. Earned success is the only real success. From this point of view the fruits of the past year's work in the electrical field may well entitle all participants, scientific, industrial or commercial, to a cheerful and gracious part in the celebration of Thanksgivng Day. Research, practical application and commercial utilization have not only maintained but have accelerated their pace, their mutual action and reaction constantly inciting to renewed and greater efforts and leading to more decisive and far reaching successes.

In the field of electrical applications reduced to commercial use the most striking feature of the year is to be found in electric street railway service. Not only has the business grown beyond all expectation in amount, but much improvement has been effected in its electrical and mechanical features. The establishment of an electric road is no longer looked upon as a formidable undertaking, nor is its operation regarded as a curiosity by the public. December 1st, a year ago there were 21 electric roads in operation in America; to-day there are 52, while 47 are under construction or contracted for. Cheap and poor line construction and ill adapted mechanical details, found too frequently in much of the early work on railways, are being discarded in new work and replaced in old (the old story, but promising to be less prolix in this instance than it has been in other cases). Much yet remains to be accomplished in electric traction, but the great gains of the closing year, technical and commercial, are abundantly apparent.

The rate at which electric motors have been installed for stationary power is scarcely less noticeable than the development of electric traction during the year. About the first of September, it was estimated that 6,000 electric motors were driving machinery in the United States. A thousand have probably been added since. It seems reasonable to estimate the number put in operation for the year at not much less than 4,000.

The use of the storage battery as a means of distribution may fairly be said to have made relatively slow advancement, while in many special cases its employment has been of great value and importance. Its problems have had and continue to enlist the close attention and skill of many able investigators and inventors, and it cannot be doubted that the moderate success thus far attained by this obviously important and necessary means of distributing electricity will be followed not long hence by such improvements as will make the accumulator a general and trustworthy instrument in electrical engineering.

The electric light, arc and incandescent, has become so familiar to everybody, even in the far western territories, that its continued rapid spread no longer attracts attention. It is expected everywhere; its absence in any considerable town is more noticed than its presence. Great activity in the installation of central station plants has prevailed during the year, especially in incandescent lighting. The success of the alternating current method of distribution in covering large areas of relatively sparse consumption has largely stimulated the demand for electric lighting in the smaller towns of the country, and has also contributed not a little towards inciting the companies whose business is based upon other methods of distribution to improving the capacity of their apparatus and the serviceableness of their lamps. The life of lamps has been materially prolonged, while a reduction has been effected in the amount of energy required per candle-power. Whatever may be thought of the policy of competition in prices, there can be no question of the general benefit of competition in the efficiency and trustworthiness of apparatus and lamps. Competition of

the former kind, while severe, has crippled only the weak, while that of the latter sort has resulted in advantage to both producers and consumers.

The practical success of the employment of alternating currents has re-acted in the laboratories of scientific research, and led to the study of new questions, or old questions in a new light; study and experiment which have already done much to clear the path of the practical electrician in his work, and which indicate the early acquisition of further electrical knowledge of great significance.

The year's scientific and practical advances are great enough for congratulation, but not great enough to induce complacent satisfaction and relaxation of effort.

ELECTRIC LIGHTING IN ENGLAND.

PROJECTS for central station electric lighting on a large scale in England are following one another with great rapidity, in London and in provincial towns as well. This recent activity is doubtless due in large measure to the improved situation of the capitalists who undertake such enterprises, consequent upon the modification by parliament, of the onerous restrictions of earlier legislation touching their privileges, and still more perhaps to the widespread and successful introduction of the alternating current and transformer method of distribution for large areas. In another column of this issue we reprint some account of the Deptford station now erecting by the London Electrical Supply Corporation, which now operates the Grosvenor Gallery station. This company will compete with the Metropolitan Electrical Supply Co., Limited, who are about to install a Westinghouse plant, as noticed in our November number. Mr. Ferranti's alternating current apparatus will be employed in the Deptford plant, which is laid out on a very large and comprehensive plan. As reported by the *Electrician*, of London, the number of lamps now wired from the Grosvenor Gallery station, is equivalent to about 35,000 10 c. p. (say 22,000 16 c. p.) lamps, a maximum of 20,000 (12,500 16 c. p.) being in use at one time. From the plans of the two companies it appears that at no distant day the central portion of London will be provided with station capacity for some 75,000 16-c. p., or 120,000 10-c. p. lamps. A third large undertaking is heralded in London—the St. James Electric Light Co.—a preliminary announcement stating that their station is designed for 20,000 lamps, of which 5,000 will be used from the start. The uneasiness of the gas companies under this state of things is exhibited in the announcement by one of them of a reduction of 3*d.* per 1,000 feet to all consumers north of the Thames. The *Gas and Water Review* says, "It would be well if gas companies would take some combined action and secure the right to supply electricity as well as gas. This is very largely done in America."

ELECTRICIANS and electrical engineers are no doubt, for the most part, too greatly occupied in worthy professional work to interest themselves very much in the problem how best to apply their art to the execution of criminals in accordance with the Act of the New York Legislature, ordaining the displacement of the gallows by the electric current after the first of January next.

The Medico-Legal Society undertook the task some weeks ago, by appointing Dr. Frederick Peterson, Dr. J. Mount Bleyer, Dr. Frank H. Ingram, and Professor R. Ogden Doremus, a committee, to report the best method of putting the new law into practice. The report of the committee was made to the society on the 14th of November, and is printed *in extenso* by an electrical contemporary, accompanied by some ghastly illustrations.

Readers who are not greatly concerned about the particular method to be employed in despatching murderers may perhaps find some interest in the following contribution to electrical knowledge, extracted from the report of the committee.

> There are several points requiring thoughtful consideration in the application of death currents to man, which we now proceed to lay before you.
>
> The average resistance of the human body is about 2,500 ohms. The most of this resistance is in the skin. It is evident, therefore, that the larger the surface of the electrode applied to the body, the greater will be the resistance. It is also a fact that the density of the current depends upon the superficial area of the electrode. A pole of small diameter will hence meet with less resistance, the passing current will be more intense, and the resulting current strength will be greater than when an electrode of large sectional area is applied.

THE decision of the Supreme Court of the United States, announced November 12th, in the suit of the Government against the American Bell Telephone Co. (on appeal from the U. S. Circuit Court, Massachusetts District, where the bill had been dismissed on the demurrer of the defendant, September 26, 1887), sustains the claim of the Attorney-General of the right to bring the suit in equity to cancel the patents in issue, remanding the case to the lower court.

This remarkable judgment seems less ominous to the Bell Telephone Company than to the interests of the owners of patents generally. Apparently all the allegations of the Attorney-General's bill, including the charges of fraud, have been passed upon in the various infringement suits by circuit and district courts, and their concurrent judgments sustaining the Bell patents were confirmed by the Supreme Court in its decision of the appealed cases last March. It seems, therefore, that the Bell company has little to fear in a trial of the government suit on the merits.

In respect to the interests of property in patents generally, the precedent made by the Supreme Court in this case is ominous because it furnishes a new weapon of attack upon profitable patents to the hands of infringers and speculators however thoroughly such patents may have been sustained in repeated trials before the national courts up to and including the judgment of the Supreme Court.

WE note with grief that two of our valued electrical contemporaries have been exchanging bad language all the way across the Atlantic. Some rather ill-natured comment on American "smartness" on the part of an English journal was too much for the equanimity of a western editor, who indignantly expressed his feelings in good set terms. This evoked further revilings from London, including antique gibes about "wooden nutmegs and clocks that won't go." Let us hope that these latter allusions are not intended to refer in any way to American dynamos and other electric lighting machinery, which not only go here, but

have already begun to go over the sea to London, where they will soon be in service on a large scale. To the allegation of "smartness" in its offensive sense, America is apparently neither more nor less amenable than Great Britain, or other commercial countries, and we may bear with unruffled composure any flings at our methods in electrical development so long as we keep up our lead of the rest of the world in the variety and extent of our electrical industries.

In respect to the contention between the Telephone company and the Common Council at Chicago, over the attempted municipal regulation of charges, fully noticed in our recent and present correspondence columns, we are advised —too late for insertion in Chicago letter—that the Corporation Counsel has announced his opinion that the city council has no right to interfere with telephone charges. He finds that no authority for such interference is conferred by the city charter. The council is balked, therefore, in its effort to regulate the business of the telephone company. It seems to be the prevailing impression that the council will petition the legislature to grant the requisite power. No action as to the attitude of the city in the meantime has been taken. Many of the aldermen favor a temporary compromise.

The Committee on Science and the Arts of the Franklin Institute desire it to be generally known that they are empowered to award, or to recommend the award of, certain medals for meritorious discoveries and inventions, which tend to the progress of the arts and manufactures.

These medals are:—1. The Elliott Cresson Medal (gold). This medal was founded by the legacy of Elliott Cresson, of Philadelphia. It will be granted, after proper investigation and report by sub-committee, either for some discovery in the arts and sciences, or for the invention or improvement of some useful machine, or for some new process, or combination of materials in manufactures, or for ingenuity, skill, or perfection in workmanship. 2. The John Scott Legacy Premium and Medal ($20 and a medal of copper). The John Scott Legacy Premium and Medal was founded in 1816, by John Scott, a merchant of Edinburgh, Scotland, who bequeathed to the City of Philadelphia a considerable sum of money, the interest of which should be devoted to rewarding ingenious men and women who make useful inventions. The premium is not to exceed $20, and the medal is to be of copper, and inscribed "*To the most deserving.*"

Upon request therefor, from interested persons, made to the secretary of the Franklin Institute, Philadelphia, full information will be sent respecting the manner of making application for the investigation of inventions and discoveries.

OBSERVATIONS.

A brief, but practical and valuable paper, was that read by Mr. W. H. Preece, before the British Association, Section A, last September, "On the C. G. S. and Practical Units of Measurement." Mr. Preece advocates the adoption of the *jóule* as a thermal unit, equivalent to 10^7 ergs, as proposed by Sir William Siemens in 1883. This, as he truly points out, would be a great help in calculation. A more important thought suggested in the same paper, is that of the extreme inconvenience which arises from the difference in value of the ampere and the C. G. S. unit of current. This is because the volt has been accepted as equal to 10^8 instead of 10^9 C. G. S. units, which of course makes the ampere one-tenth of the C. G. S. unit current. Nobody seems to know a really first-class reason in favor of the present value of the volt, but the one which Mr. Preece says has been given, is that the volt represents very nearly the E. M. F. of a Daniell cell; which is, of course now, no reason at all.

He would like the British electricians when they attend the conference at Paris, next year, to be armed with an opinion of the British Association, that 106.3 c. m. represents more nearly than 106, the true ohm; and that the volt should be made equal to 10^9 C. G. S. units of E. M. F.

. . .

The profession has grown so immensely since 1882, when we were first introduced to the ampere, that to many of the fraternity that period must look like antiquity.

There are, however, a goodly number still at the fore, who well remember that it came as a kind of shock to us, who had grown familiar with a unit of current called the *Weber* (or as it was sometimes barbarized, *Veber*), to hear that henceforth we were to know that name no more; that the same unit of current must hereafter, if we wished to be in good form, be called the *ampere*.

It seemed clumsy for a while, but the tremendous influx of new men who had nothing to unlearn, carried the day.

. . .

And after all was it not well to commemorate the French scientist, who established the science of electro-kinetics by associating his name with the unit of current. We would not now have it changed. How much the simple formula $C = \frac{E}{R}$ means to all of us. All honor to him who worked out the laws of currents without its aid.

These observations contained a word on Green, last month. Let us take a look at Ampere this month.

André-Marie Ampere.—Born January 22d, 1775. Died June 10th, 1836, aged 61. In 1793, his father died by the guillotine, a victim of the Revolution.

As an electrician his great work, and that upon which his fame mainly rests was his exposition of the science of electro-magnetism, or electro-kinetics, which indeed he may be said to have founded. He first heard of Oersted's discovery that a magnetic needle may be deflected by a voltaic current, on September 11th, 1820, and within eight days thereafter, on the 18th of the same month he presented a complete analysis and explanation of the phenomenon, a masterly piece of work.

He also formed and adopted the theory that all magnets, including the earth, were produced by the continuous circulation of electric currents in closed circuits around them.

In October, 1820, he suggested an electric telegraph in which magnets were to be deflected by the action of conducting wires, one for each letter, each wire being connected with a key at the transmitting station, which when depressed would make contact with a battery. This however never advanced beyond the region of suggestion.

A more important work was his invention of the double or astatic needle, which is described in his memoir of 1821. This idea is usually ascribed to Cumming or Nobili, and indeed Cumming invented a very similar device shortly thereafter.

Ampere was also the author of the celebrated expedient of determining the position of the needle in relation to the current, by imagining a man swimming in the stream.

Those wishing to know more of this philosopher can profitably refer to the Encyclopedia Brittanica article on Ampere; to "A History of Electric Telegraphy," by J. J. Fahie, pp. 275–303, and to Brennan's "Electricity and its Discoverers."

ARTICLES.

DYNAMO REGULATION BY MEANS OF A THIRD BRUSH.[1]

BY EDWARD CALDWELL, A. B., M. E.

THE following study of methods of third brush regulation of series dynamos for *constant current*, was taken up at the suggestion of Professor Nichols. During the progress of the experimental work it was discovered that a similar method of regulation might be applied to a series-wound dynamo for the production of a *constant electromotive force*. The investigation was made to include, therefore, the applicability of this method of regulation to a series-wound dynamo, both for a constant current and a constant electromotive force.

The dynamo used in this work was a small series-wound machine, with two upright field magnets of the Edison type and a Gramme armature. The cores and yoke were of the best Norway iron. The principal dimensions and constants of the machine were as follows :—

Diameter of armature, outside..............	$4\frac{3}{4}$ inches
Length " " "	$2\frac{1}{4}$ "

A third brush, held by an independent brush holder, was placed upon the commutator between the regular brushes. This could be set at any desired angle in advance of the positive brush, a pointer indicating the angle upon the graduated circumference of a wooden ring placed concentrically with the shaft. Another pointer indicated in a similar manner the angular lead of the regular brushes. Each of these pointers was set at zero of the graduated scale when the brush which carried it rested at the upper end of the vertical diameter of the commutator—a point midway between the edges of the pole-pieces.

The field was explored for distribution of potential around the commutator by a modification of a method described by Professor Brackett, in a paper read before the American Institute of Electrical Engineers in 1884, and published in vol. i. of the *Transactions*.

The current was measured by a tangent galvanometer, the coil being formed of a single ring of copper, 50 centimeters in diameter, and of rectangular cross-section. Its constant was determined by comparison with the large standard tangent galvanometer, in the Magnetic Observatory of Cornell University. The deflections could easily be read to tenths of a degree.

The E. M. F. was measured by an Ayrton and Perry voltmeter which had previously been calibrated. The voltmeter was shunted across the regular brushes of the machine.

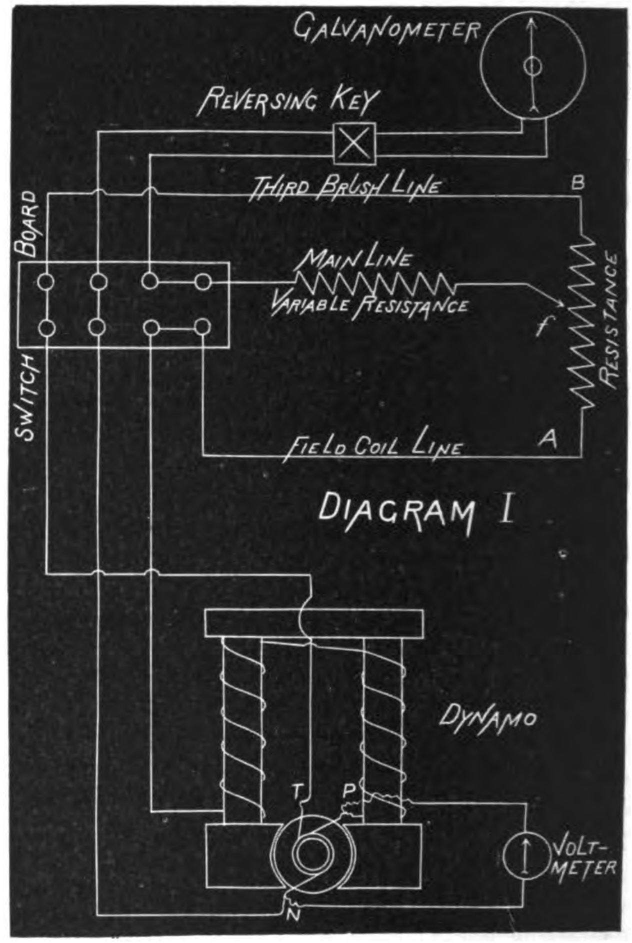
The resistances used in the external circuits were made of german-silver wire coiled in the form of a spring and stretched upon upright wooden frames. By means of a copper hook, contact could be made at any desired point. These coils were standardized by comparison with the coils of an Elliott Bros. resistance box of the dial pattern.

The arrangement of the apparatus during the first portion of this investigation differed from that of the Waterhouse Electric Co., in their system of third brush regulation for constant current[2], only in that the point of contact of the main line with the resistance coils of the regulator was varied by hand instead of by automatic means.

1. Revised abstract of graduating thesis, Sibley College, Cornell University, June, 1888.

2. See *Electrical World*, Sept. 29, 1888.

The connections used are shown in diagram I. The switch-board contained eight small mercury cups—two each for the terminals of the galvanometer, the third brush line, and the main line, and was so arranged that the galvanometer could be placed in any one of the three circuits.



The machine was first run at 2,500 revolutions as an ordinary series machine with two brushes, these being adjusted to the non-sparking position with a lead of about 12.° Table 1 gives the data obtained from which the characteristic curve in plate A is plotted.

It will be noticed here that a very small amount of current is sufficient to saturate the field magnets, because of the very large number of turns of wire on the field coils.

With the third brush upon the commutator a study was made of the effect of increasing the angular distance between the third and positive brushes. The tabulated results are given in tables 2 to 6. The third brush remained fixed through each set of observations, and the main brushes, at a lead of 12°, through all the five sets. The resistance between the third and positive brushes was 21 ohms.

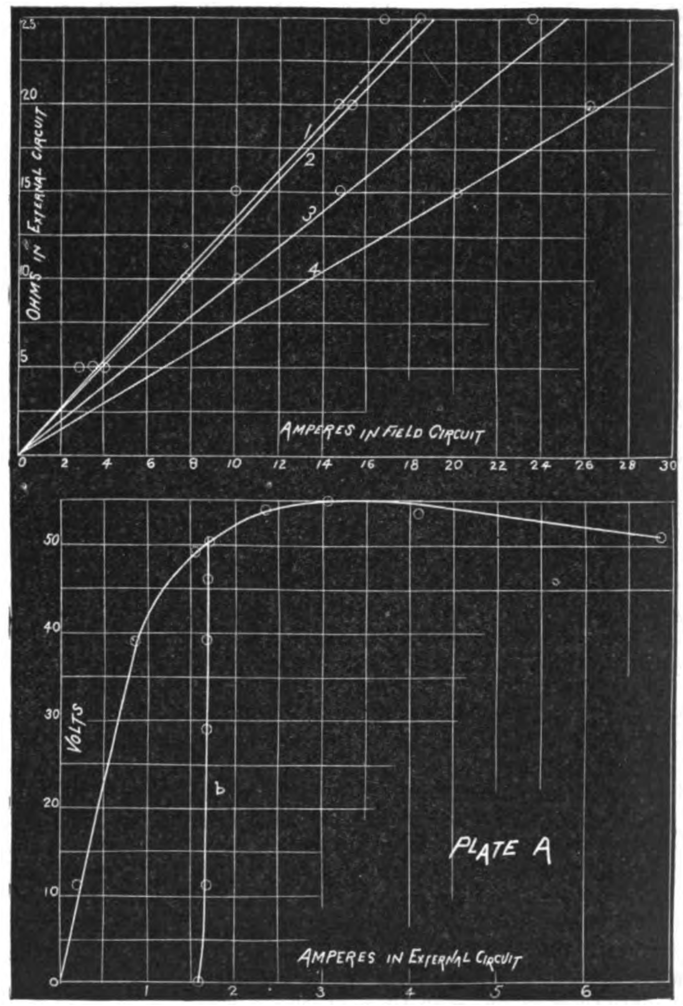
The curves of relation of E. M. F. and current, of which curve *b*, plate A, is an example, need not be plotted, as an inspection of the tables will show, that within the limits of regulation, the curves are superposed vertical lines, if the volts be taken as ordinates and the amperes as abscissæ. Curves 1 to 4, plate A, are plotted from tables 2 to 5.

These curves are straight lines, and they show that the condition necessary to constancy of current in a series dynamo, namely, direct proportionality of external resistance and current in the field coils, has been secured. They also show that the greater the lead given to the third brush, the greater the field current necessary to keep the external current constant, the external resistance being the same. This will also be seen by a comparison of columns 3 and 7 in tables 7 to 10. These tables are compiled from tables 2 to 6.

But the most interesting as well as the most important phenomenon shown by all of these tables alike, is the change of sign of the current in the third brush line. Under some conditions the third brush acts as a positive brush, and under others as a negative.



Tables 2 to 6 show, (1) that with each position of the third brush, on increasing the external resistance, the current in the third brush circuit at first decreases, becomes zero, and again increases in the opposite direction; and, (2) that the further the third brush is in advance of the positive, the higher is the current in the third brush line at first, the sooner the zero point is reached, and the higher the current rises in the opposite direction.

Tables 7 to 10 show, (1) that with advance of the third brush, the external current and resistance being kept constant, the E. M. F. continues to rise while the current in the third brush line gradually decreases, passes through zero, and again increases in a negative direction; (2) that this zero point is also the point of maximum additional

resistance in the field, and of minimum additional resistance in the third brush line; and, (3) that this zero point is reached sooner the higher the external resistance.

It was at first thought that these changes might be due to a distortion of the neutral line of the armature, since with each change in external resistance there was a corresponding change of strength of field, while the current flowing up through the armature from the negative brush remained constant. An exploration of the field, however, by the method alluded to, showed that under extreme variations of current in the field, the neutral line did not change position as much as 10°,—an amount quite insufficient to account for the changes shown in the tables.

It will be noticed that the application of the third brush destroys the symmetrical flow of current in the armature. If the third brush be positive it will take off a part of the current flowing up on that side of the armature, and the coils lying between the third and positive brushes will have less current than the other coils. But if the third brush be a negative, the current returning to the armature by the third brush line will be added to the coils lying between the third brush and the positive. Neither will the current flowing up on one side of the armature be equal to that on the opposite side, since the resistances of the two paths offered to the current are not equal. The result of this unequal distribution will be, in extreme cases, to throw the neutral points of the armature off the ends of a diameter and on that side of a diameter where the coils are traversed by the weaker current. If, however, as was the case with the machine used in this investigation, the magnetic moment of the field is very great as compared with that of the armature, this effect is inappreciable.

But these variations of current in the third brush line may be satisfactorily explained without reference to the distortion of the diameter of commutation. It is a well-known fact that the total E. M. F. generated in the armature coils increases around the commutator from the negative brush to the positive, each coil adding its share to that induced in the coils preceding, and that the E. M. F. again falls, through the same range, from the positive brush around the external circuit to the negative brush.

Let E_d be the drop of potential between the positive brush and the point at which the third brush line joins the main circuit, and let E_1 be the rise of potential between the third and positive brushes,—that is, the E. M. F. induced in the coils which lie between these brushes.

It is evident that if $E_d = E_1$, no current will flow in the third brush line, its two ends being at exactly the same potential. But if $E_d > E_1$, the third brush will be at a point of higher potential than the other end of the third brush line, and current will flow *out of* the armature through the third brush. If $E_d < E_1$, the reverse effect will be produced, and current will flow along the third brush line *into* the armature.

Now $E_d = C' R'$, where C' and R' are respectively the current and resistance of that part of the circuit between the positive brush and the junction of the third brush line with the main line. Also,

$$E_1 = \frac{2}{\pi}\, w\, H'\, A'$$
$$= 4\, n\, H'\, A'.$$

A' being the "equivalent area" of the coils lying between the third and positive brushes; H', the strength of field; w, the angular velocity; and n, the number of revolutions per second of the armature.

There will be equilibrium between the ends of the third brush line when $E_d = E_1$, that is, when

$$C' R' = 4\, n\, H'\, A'.$$

The speed remaining constant, this equation shows that any one of three changes will make $E_d > E_1$, and so make the third brush positive.

(1) *Increase of R'.*
This will occur if the finger, *f*, diagram i., be moved toward the point B. This change will produce a corresponding decrease of C' and H', but below the saturation point these practically vary in direct proportion, and will not change the value of the equation.

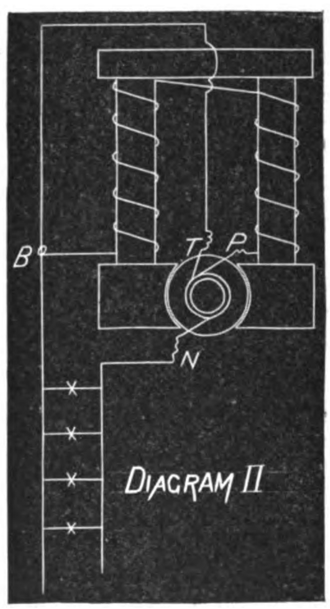
(2) *Decrease of A'.*
This may be done by bringing the third and positive brushes nearer to each other, thus decreasing the number of coils between them.

(3) *Increase of C'*, the field magnets being saturated.
If H' remain practically constant because of the saturation of the iron, an increase of C', caused by a decrease of the resistance of the external circuit, will make $E_d > E_1$.

The three opposite changes will make $E_d < E_1$, viz.:—
(1) *Decrease of R'.*
(2) *Increase of A'.*
(3) *Decrease of C'*, the field magnets being saturated so that H' remains constant.

A change of speed, n, would produce a complex change in all of the factors, except A'. All of the variations of current in the third brush line may be traced to one or more of these causes.

It will be noticed that the difference of potential between the main brushes is always the same—between 50 and 51 volts—when the current in the third brush line changes sign. This is the point at which the new characteristic crosses the characteristic of the regular series machine, as shown in plate A, where the characteristic curves from tables 1 and 2 are plotted together. When the third brush is positive it robs the field coils of a part of their current and adds this to the main line current, and when it is negative it diverts a portion of the current from the main line, adding it to the field circuit line.



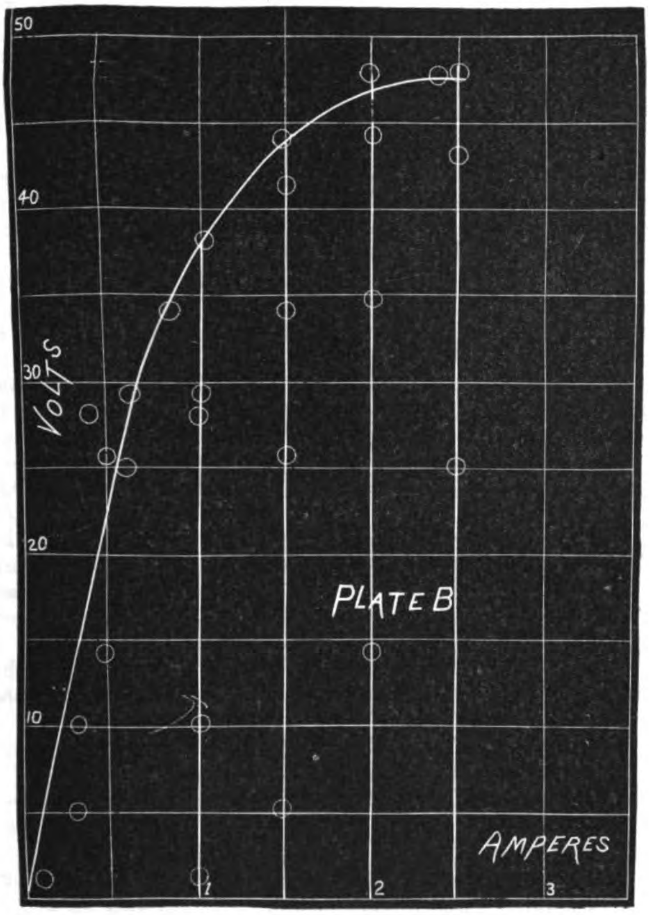
It will also be noticed that curves plotted between field current and E. M. F. from tables 2 to 6, coincide with the characteristic from table 1. This would necessarily be so, since in table 1 the external current is also the field current.

No higher E. M. F. can be reached on the constant current curve than that obtained from the machine worked as an ordinary series dynamo, the limit being reached as soon as the iron of the field magnets becomes saturated.

The horizontal distance between corresponding points on the constant current curve and on the curve of E. M. F. with field current, measures the amount of current flowing in the third brush line at that point, and also shows whether it is positive or negative.

It is evident that the point of crossing of the two characteristics—that is, the point at which the current in the third brush line becomes zero, will depend upon the *amount* of the constant current in the external circuit. Tables 11 to 14 give the data obtained when the external current was held respectively at 1.0, 1.5, 2.0 and 2.5 amperes. The points obtained by plotting field current with E. M. F. fall, as before, upon a common curve, as shown in plate B, and the constant current curves for 1.0, 1.5, 2.0 and 2.5 amperes cross this curve at 38, 44, 47 and 47.5 volts E. M. F. A curve for .5 of an ampere would cross the characteristic at about 22 volts.

Below the saturation point of the iron, the relation between current in the third brush line and E. M. F. is one of direct proportion. When the saturation point is reached, current in the third brush circuit may increase indefinitely without increase of E. M. F.



No very large *negative* current is obtained in the third brush line until the third brush is 90° or more in advance of the positive. This would seem to indicate that the constant-current characteristic cannot be carried much, if any, above the regular series characteristic unless the third brush has a very large lead, and this is objectionable because of very bad sparking at the third brush.

This arrangement is in reality equivalent to a compound wound dynamo in which one set of field coils is made to carry the current for both the series and shunt coils of the usual type of compound wound machine. Referring to diagram i, and the last line of table 4, it is clear that the field coils act as *series* coils in carrying a current of 1.70 amperes from P, the positive brush, around the external circuit to the negative brush, N, and that at the same time, they act as *shunt* coils in carrying .65 of an ampere from P, around the field magnets and back to T, the third brush. There is, however, this further distinction to be made between this arrangement and the usual type of compound dynamo,—that that part of the field current which partakes of the character of a shunt becomes zero under certain conditions of the external circuit, and that beyond this point the shunt circuit acts as a differential coil wound upon the field magnets. This is effected, not by an opposing current being sent around the field, but by the shunt becoming a *shunt around the series field coils*, thus depriving them of a part of the current they would otherwise receive, and so weakening the field. This is shown by the first line of table 4, where, of the 1.70 amperes in the external circuit the field coils carry but .35, while a current of 1.35 amperes is shunted around the field by the third brush line and added to the current in the main circuit. Though common enough in motors, the writer is not aware of any other case in which a differential coil or anything analogous to it is applied to a generator.

The arrangement then embodies at once the principles of three distinct types of dynamos, the type used being determined solely by the resistance of the circuit if the external current be kept constant. In keeping a constant external current, however, the resistance of the series field changes.

These three types are :—

1. Series dynamo + differential shunt coils (or rather what has the same effect as differential shunt coils).

This type is brought into use when the third brush is at a higher potential than the junction of the third brush line with the main line and a portion of the total current of the armature is diverted from the field coils, decreasing the strength of field.

2. Plain series dynamo.

This is the type made use of when both ends of the third brush line are at the same potential and the current flowing in it is *nil*, which occurs at the point of intersection of the two characteristics.

3. Series dynamo + cumulative shunt coils.

This occurs when the junction of the third brush line with the main line is at a higher potential than the third brush and current flows into the armature at the third brush.

It should be noticed that in this combination the total resistance of what corresponds to the shunt circuit of the field, including the resistance of the field coils and whatever resistance may be placed between the third brush line and the field line, is a constant, while the resistance of what corresponds to the series circuit of the field is variable, being changed by the movement of the finger, *f*, diagram i, along the resistance, *A B*.

The requirements for constant potential regulation are radically different from those necessary for constant current. Recurring again to Professor S. P. Thompson's fundamental equation of the dynamo,

$$E = 4\,n\,A\,H,$$

where n and A are both constant, it is evident that if E is to be a constant, H must also be a constant. Hence, for constant potential regulation the exciting current of the field coils must be a constant.

It is believed that the method here described for obtaining this result has not before been applied for this purpose. The arrangement is a very simple one, as shown in diagram ii. The third brush line passes through a low resistance and is joined to the main line at the positive terminal of the machine,—just outside the field coils. In this case either no resistance or a very low one is placed between the third and positive brushes, and no automatic arrangement is necessary, as the point of junction is a fixed one. Diagram iii shows the connections as used in the experimental work.

The effect of using different resistances in the third brush line is shown by tables 15 to 19, and curves 1 to 5, plate C, plotted from these tables. The third brush remained fixed at 36° in advance of the positive brush, this being given as before, 12° lead. Curve 6, of the same plate is plotted from table 20, and is the characteristic of the machine run as a series dynamo, reduced to the same speed as tables 15 to 19.

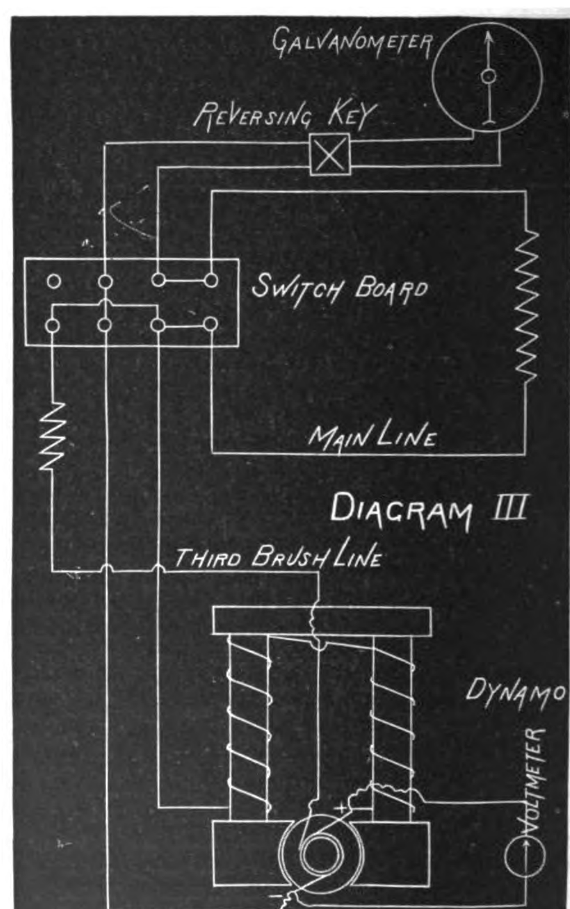
These curves and tables show: (1) that the current in the third brush line is, at first, with high external resistances, negative, having its highest value when the external resistance is infinite or when the main line circuit is open; that with decreasing external resistances it gradually decreases, passes through zero, and again rises in the opposite direction; (2) that the point at which the third brush current becomes zero is independent of the resistance in the third brush line, becoming zero in each curve at exactly the same external resistance, and that this zero point is the point at which the new curve crosses the series characteristic; (3) that increase of resistance in the third brush line reduces the regulating power of the third brush, the curve at the limit coinciding with curve 6; (4) that increase of resistance in the third brush line decreases the field current, and consequently the E. M. F., but that the external current is practically independent of the resistance in the third brush line; (5) that the most constant E. M. F. is produced when the third brush line has a resistance of about three ohms—in this case about twice that of the field coils. This resistance, however, will vary, not only with the resistance of the field coils, but also with the angular advance given to the third brush and with the amount of current necessary to produce saturation—that is, with the quality and quantity of iron in the cores.

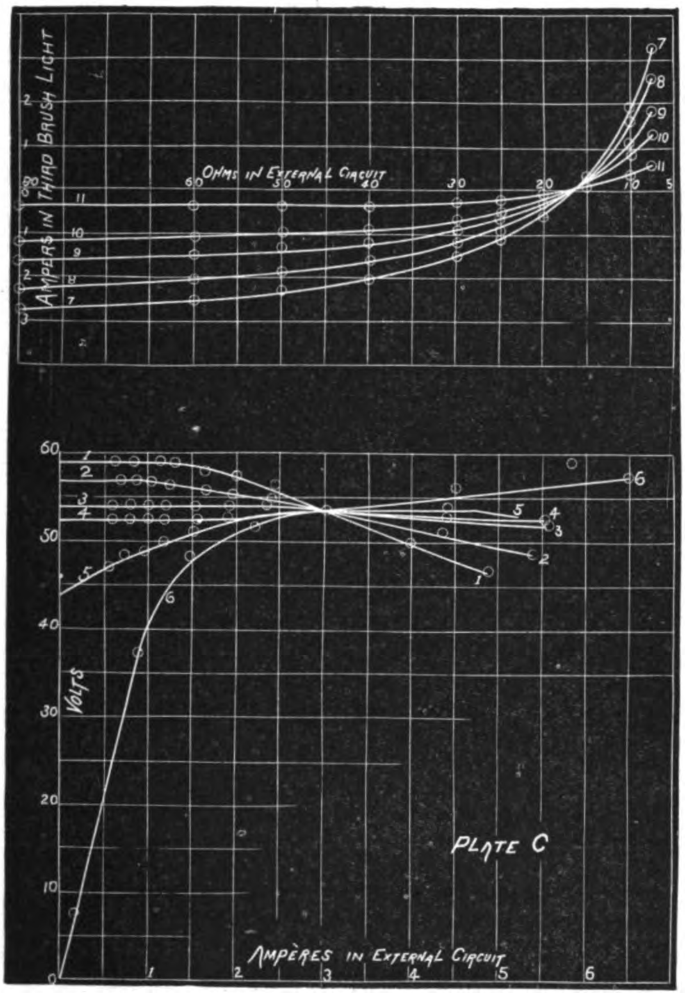
The explanation of these phenomena is slightly different from that already given for the changes observed in the case of constant current regulation. The same equation, however, is applicable. Using the same symbols, as before, equilibrium will exist between the ends of the third brush line, when $E_4 = E_1$, or $C' R' = 4 n H' A'$. In this arrangement R', which is here the resistance of the field coils only, remains a constant. A decrease of A' by bringing the third and positive brushes nearer each other, or, within certain limits, an increase of C', will make $E_4 > E_1$ and make the third brush positive. If now A' remains constant and C' be increased by a decrease of the external resistance, H' will increase in direct proportion as long as the iron of the field magnets is in the unsaturated condition, and there will be no change in the value of the equation, $E_4 = E_1$. But as soon as the saturation point is reached, H' becomes practically a constant, and further increase of C' will make $E_4 > E_1$ and the third brush positive. In tables 15 to 19 the field magnets are fully saturated when $E_4 = E_1$, and hence *any* increase of C' makes $E_4 > E_1$. Had A' been much smaller this result would not have been obtained.

The two opposite changes will make $E_4 < E_1$ and the third brush negative, viz: an increase of A_1' or a decrease



of C'. A decrease of C', however, will produce this result only when, as before, the iron is fully saturated. This is shown in the first part of table 19, where the field current was not sufficient to produce saturation of the magnets

and, as a result, the current in the third brush line remains practically unchanged while C' undergoes considerable variation.



It is evident that the potential of the two extremities of the third brush line is independent of the resistance of the line, and hence any variation in this resistance will have no effect upon the point at which its two ends will be at equal potential. It does, however, determine the amount of current flowing in this line, and hence the amount flowing in the field coils; since when the third brush is negative it adds its current to that of the field coils, and when it is positive the current in it is shunted *from* the field coils, as in the constant current regulation. This resistance must be low enough to allow of complete saturation of the field magnets.

Here, again, we have an arrangement which is in reality equivalent to a compound wound dynamo. Referring to diagram ii and the first line of table 17, it will be seen that the field coils perform the part of series coils in carrying .6 of an ampere from the positive brush, P, around the external circuit to N, and at the same time, as shunt coils, carry 1.63 amperes from P around the field magnets to T, the third brush. The same three types of dynamos are here brought into use, viz:—

1. Series dynamo+cumulative shunt coils.
2. Plain series dynamo.
3. Series dynamo+"differential shunt" coils, and the conditions under which each is brought into use are precisely like those already met with in regulation for constant current.

As was pointed out in the discussion of the constant current regulation, the application of the third brush necessarily interferes with the symmetrical flow of current in the armature, those coils lying between the third and positive brushes carrying more or less than the other coils, according as the third brush is negative or positive. In properly constructed dynamos this should produce no detrimental effect. It should, however, be taken into account in dynamo design when computing the size of armature wire from the amount of current it is to carry, for it is evident that in this case one-half the total current in the external circuit is not the maximum current which the armature coils must carry. A similar remark applies to the size of wire for the field coils.

A decrease of the resistance of the field coils would decrease the loss of potential between the positive brush, P, diagram ii, and the point B, and, the potential of T remaining constant, would increase the negative current in B T, and, other things being the same, the lower the resistance of the field the lower the resistance of the external circuit must be made before B and T are brought to the same potential, or in other words, before the new characteristic crosses the series characteristic; and if this point is not reached within the limits of the machine only the first of the three types of dynamos mentioned above is made use of. The same effect is produced by giving increased advance to the third brush, thus lowering its potential. Increased resistance of the field or decreased advance of the third brush will produce opposite effects. It will be found that whatever the field resistance or the advance of the third brush, there will be a corresponding resistance for the third brush line (and this in conjunction with the field coils may be regarded as the shunt circuit of a compound dynamo), for which the machine will produce a constant E. M. F.

Professor S. P. Thompson has observed that the efficiency of any compound wound dynamo for constant E. M. F. is very nearly a constant. Using his equation for efficiency, this is very nearly obtained from table 19 and curve 5, plate C, and this is probably very near the true curve for constant E. M. F. at the *terminals* of the machine, the volts here being the difference of potential between the brushes.

It is hoped that at some future time an experimental study, similar to that described above, may be made of third brush regulation for electric motors for both constant current and constant potential circuits. The field is an inviting one, and cannot fail to be productive of useful and practical results.[1]

BOSTON, Mass., Nov. 17, 1888.

A POCKET GALVANOMETER.[1]

BY AIKITU TANAKADATE.

(Assistant to the Professor of Physics, Imperial University, Tokio, Japan.)

(*Concluded from page 520.*)

§ II. FLAT COIL POCKET GALVANOMETER.

I NOW pass to the description of the flat coil pocket galvanometer, which may in virtue of its compactness and simplicity of construction be found useful for some purposes, although it can not, of course, take the place of circular coils when absolute determinations of electro-magnetic constants are required. One such instrument is represented in figure 8. It is essentially the same as an old form of current detectors, constructed, however, with due regard to the proportional dimensions which theory shows to be best.

The following calculation of the proper distance between two rectangular coils is made not so much for the sake of the flat coil galvanometer as for the sake of the internal coil mentioned above (page 517) and described in detail below (page 568).

1. See U. S. Patent Specifications Nos. 387,194 and 387,195, of July 31, 1888.

1. From the Journal of the Science College, Imperial University, Japan Vol. I.

Let $2a$ be the distance between the two coils.
" $2b$ " height of the coils.
" $2c$ " length "

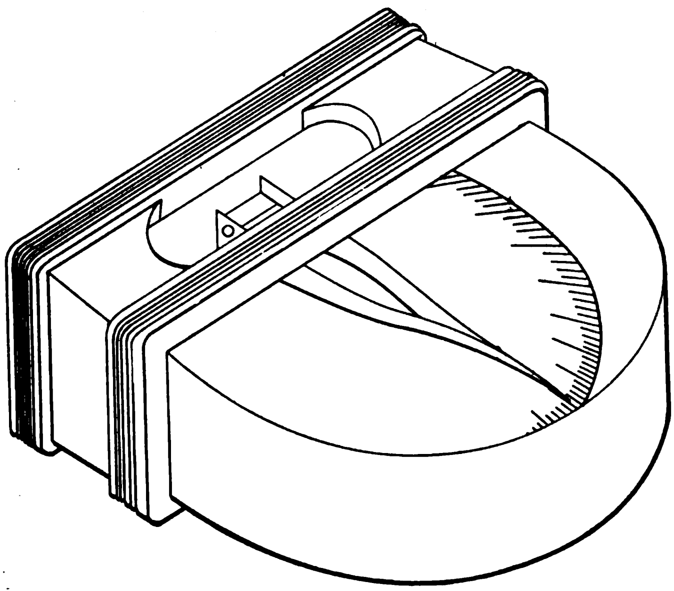


Fig. 8.

Let x, y, z, be the co-ordinates of any point referred to the centre of the coils as origin, axes being parallel to a, b, c.

Let ξ, η, ζ be the co-ordinates of any corner of the coils referred to any point x, y, z as origin, so that

$$\xi + x = a, \qquad \eta + y = b, \qquad \zeta + z = c.$$

Then the potential at any point due to unit current is the sum of the solid angles subtended by the coils, or

$$V = \Sigma \sin^{-1} \frac{\eta \zeta}{\sqrt{\xi^2 + \eta^2} \sqrt{\xi^2 + \zeta^2}} = \Sigma\, \Omega \text{ say}$$

Σ meaning the summation for eight corners, there being four to each coil. Now,

$$\frac{\delta^n}{\delta x^n} = (-1)^n \frac{\delta^n}{\delta \xi^n}; \quad \frac{\delta^n}{\delta y^n} = (-)^n \frac{\delta^n}{\delta \eta^n}; \quad \frac{\delta^n}{\delta z^n} = (-1)^n \frac{\delta^n}{\delta \zeta^n}.$$

Hence,
$$F = -\frac{\delta V}{\delta x} = \Sigma \frac{-\eta \zeta}{\rho_0} \left(\frac{1}{\rho_1^2} + \frac{1}{\rho_2^2} \right)$$

where $\rho_0 = \sqrt{\xi^2 + \eta^2 + \zeta^2}$; $\rho_1 = \sqrt{\xi^2 + \eta^2}$;
$\rho_2 = \sqrt{\xi^2 + \zeta^2}$

The force at the centre of the coils will be given by making $\xi, \eta, \zeta = a, b, c$ respectively and multiplying the result by n, if n be the number of turns of wire in the coil.

The increment of force at any displaced point δx, δy, δz, is given by the equation (odd terms disappearing as before),

$$\Delta^2 F = \frac{1}{\underline{|2}} \left\{ \frac{\delta^2 F}{\delta x^2} (\delta x)^2 + \frac{\delta^2 F}{\delta y^2} (\delta y^2 + \frac{\delta^2 F}{\delta z^2} (\delta z^2 \right\} + \frac{1}{\underline{|4}} \left\{ \cdots\cdots\cdots \right.$$

but, since

$$\frac{\delta}{\delta x} \Delta^2 V = \frac{\delta^2}{\delta x^2} \frac{\delta V}{\delta x} + \frac{\delta^2}{\delta y^2} \frac{\delta V}{\delta x} + \frac{\delta^2}{\delta z^2} \frac{\delta V}{\delta x} = 0$$

it is necessary and sufficient that any two of $\delta^2 F / \delta x^2$, $\delta^2 F/\delta y^2$, $\delta^2 F/\delta z^2$ should vanish simultaneously, in order that they all may vanish at the same time.

Thus we have

$$\frac{\delta^2 F}{\delta y^2} = \Sigma \frac{\eta \zeta}{\rho_0} \left\{ \frac{3}{\rho_0^2} \left(1 - \frac{\eta^2}{\rho_0^2}\right) \left(\frac{1}{\rho_1^2} + \frac{1}{\rho_2^2}\right) + \right.$$

$$\frac{\delta^2 F}{\delta z^2} = \Sigma \frac{\eta \zeta}{\rho_0} \left\{ \frac{3}{\rho_0^2} \left(1 - \frac{\zeta^2}{\rho_0^2}\right) \left(\frac{1}{\rho_1^2} + \frac{1}{\rho_2^2}\right) + \right.$$

$$\left.\begin{array}{l} \left. \dfrac{6}{\rho_1^4} - \dfrac{4\eta^2}{\rho_0^2 \rho_1^4} - \dfrac{8\eta^2}{\rho_1^6} \right\} = 0 \\ \left. \dfrac{6}{\rho_2^4} - \dfrac{4\zeta^2}{\rho_0^2 \rho_2^4} - \dfrac{8\zeta^2}{\rho_2^6} \right\} = 0 \end{array}\right\} \text{(A)}$$

which at the centre of the coils (ξ, r, ζ being a, b, c) reduces to

$$\frac{\delta^2 F}{\delta y^2} = \frac{b c}{(a^4 + b^2 + c^2)^{\frac{5}{2}} (a^2 + b^2)^3} \left\{ 12 a^6 + (21 b^2 + 15 c^2) a^1 + (6 [b^2 + c^2]^2 - 2b^2 c^2) a^2 - b^2 (b^2 + c^2)(3b^2 + 2c^2) \right\} = 0$$

$$\frac{\delta^2 F}{\delta z^2} = \frac{b c}{(a^2 + b^2 + c^2)^{\frac{5}{2}} (a^2 + c^2)^3} \left\{ 12 a^6 + (21 c^2 + 15 b^2) a^4 + (6 [b^2 + c^2]^2 - 2b^2 c^2) a^2 - c^2 (b^2 + c^2) (3c^2 + 2b^2) \right\} = 0$$

Unless these two equations are simultaneously satisfied, the three partial differential coefficients will not vanish. Eliminating a between the two equations we find that the only admissible cases are when $b = c$, and either b or $c = \infty$. Thus it seems that $\Delta^2 F$ can not be made to vanish entirely except for the case of a square, and four infinite parallel straight currents. But when either b or c is great compared with the other, the partial differential coefficient with respect to the greater will be comparatively small as may be judged from the equations (A). Hence for such cases, if $\delta^2 F / \delta^2 x = 0$, both the others must be small.

But since $\dfrac{\delta^2 F}{\delta x^2} = -\left(\dfrac{\delta^2 F}{\delta y^2} + \dfrac{\delta^2 F}{\delta z^2}\right)$* we find from the above two equations

$$\begin{aligned} \frac{\delta^2 F}{\delta x^2} \propto 24a^{12} &+ 72 (b^2 + c^2) a^{10} + [93 (b^4 + c^4) + 146 b^2 c^2] a^8 \\ &+ 8 (b^2 + c^2) [9 (b^4 + c^4) + 4b^2 c^2] a^6 \\ &+ 3 (b^2 + c^2)^2 [11 (b^4 + c^4) - 10b^2 c^2] a^4 \\ &+ 2 (b^2 + c^2)^2 [3 (b^4 + c^4) - 7b^2 c^2] a^2 \\ &- b^2 c^2 (b^2 + c^2)^2 [2 (b^4 + c^4) + b^2 c^2)] = 0 \end{aligned}$$

from which a is to be found for any given value of b and c, the sides of the coils. Since the equation is homogeneous, we may take either b or c as unit of length and measure the other lengths in terms of it. Thus, if we take b (half the height of the coils) as the unit, and express a and c in terms of it, we have all the possible cases brought out by varying c from 1 to ∞. Examining the above equation, we find that there is only one variation of sign among the coefficients of a whatever b or c may be. Hence this equation has only one pair of real roots.

Putting $a = \dfrac{1}{\sqrt{2}} b$, and $a = \dfrac{1}{2} b$ successively the expression changes sign once, so that the positive root of this equation lies between .5 and .71 whatever be the values of c/b. Dividing the equation by its last term we see that

* The equation $\delta^2 F/\delta y^2 + \delta^2 F/\delta z^2 = 0$ shows that at the origin F, considered as a function of y and z, is a minimax with respect to those variables; when $b = c$, this becomes what may be called a *flat point*, and for $b = \infty$, a *flat line*.

the higher powers of a rapidly converge when c increases. When $c = \infty$ the equation reduces to

$$3a^2 - b^2 = 0$$

which agrees with the previous result. When $b = c = 1$ it reduces to

$$4\,(a^2 + 1)^3\, 6a^6 + 18a^4 + 11a^2 - 5) = 0$$

as might be found by an independent calculation.

Since a knowledge of the solution of this equation will serve as a guide in the construction of such galvanometers, I give the following table of its roots for several values of c/b together with the values of the field and the proportional decrement of force at the point $\delta x = \frac{1}{2} a$. From these numbers we can at once judge of the uniformity of the field.

Value of c/b.	a (root).	$2\tan^{-1}\frac{a}{b}$.	$F_0 - \frac{8bc}{r_0}\left(\frac{1}{r_1^3} + \frac{1}{r_2^3}\right)$	$\Delta^2 F/F_0$ at $x - \frac{1}{2}a$.
1	.54451	57° 8′	8.144	.00085
$\sqrt{2} - 1.4$	.60040	61° 58′	7.151	.00081
2	.59786	61° 42′	6.681	.00077
3	.58898	60° 34′	6.365	.00074
4	.57980	60° 13′	6.232	.00074
5	.57843	60° 6′	6.148	.00074
10	.57742	60° 0′	6.089	.00074
∞	.57735	60° 0′	6.000	.00075*

* For Helmholtz's arrangement $\Delta^2 F/F_0 - .00077$.

The values of F_0 for any actual case are to be obtained by dividing the above number by the number expressing half the height of the coils in centimeters, and multiplying by the number of turns of wire in the coil. From the table it is seen that when the length, c, exceeds 5 times the height b, the action of the coils is not far from that of the four infinite parallel currents already treated. This justifies the experiment described at the close of the first section of the paper. Further, we see that *the assumption for a large magnetic shell made in the beginning of the paper is practically correct*, if the straight part of the circuit extends more than 5 times the distance between the upper and lower magnets ($c/b = 10$) on each side of the instrument, and if the length of each magnet is not less than $5c$.

In practice, however, the coils are of finite section whereas the above results refer to coils of infinitesimally small section. So long as the depth and width of the sections of the coils are small fractions (say 1/10) of the height of the coils or of their distance apart, we may, without sensible error take the centres of the sections for the positions of simple equivalent coils of infinitesimal section.

If the depth of the section is small and the width finite, the force at the centre of the coils is got by a process of ordinary integration. Thus if the number of turns of wire per centimeter be n, we have with the same notation as before,

$$F = \Sigma \int_{a_1}^{a_2} \frac{\delta \Omega}{\delta x}\, n\, dx$$

$$= \Sigma\, n \Big[\, \Omega \,\Big]_{a_1}^{a_2}$$

when a_1 and a_2 are the distances of the internal and external faces of either coil measured from the point half way between the two coils. Hence in order that the effect of eccentric displacement may be small, we have

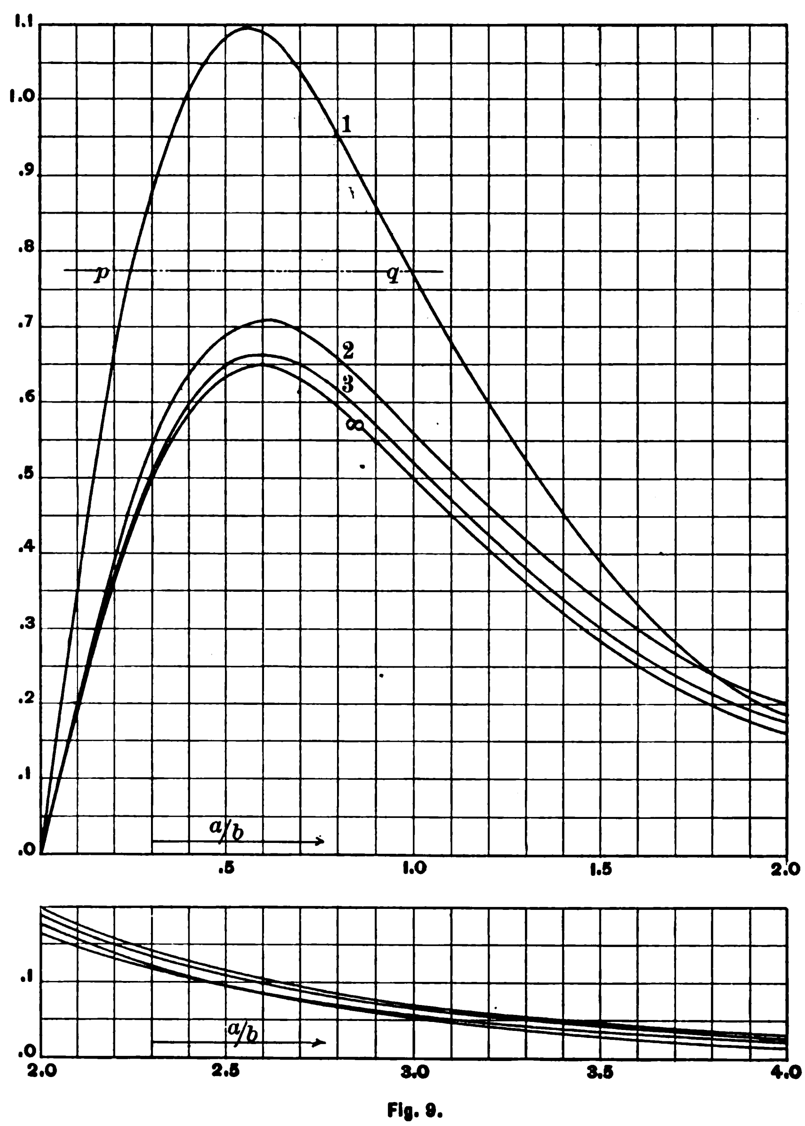

Fig. 9.

$$\frac{\delta^2 F}{\delta x^2} = \Sigma \left\{ \left(\frac{\delta^3 \Omega}{\delta x^3}\right)_{a_1} - \left(\frac{\delta^3 \Omega}{\delta x^3}\right)_{a_2} \right\} = 0$$

$$\frac{\delta^3 \Omega}{\delta x^3} = \frac{\delta^3}{\delta \xi^3} \sin^{-1} \frac{\eta \zeta}{\sqrt{\xi^2 + \eta^2}\ \sqrt{\xi^2 + \zeta^2}}$$

$$= \frac{\xi \eta \zeta}{\rho_0} \left\{ \frac{1}{\rho_0^2} \left(\frac{1}{\rho_1^2} + \frac{1}{\rho_2^2} \right) + 2 \left(\frac{1}{\rho_1^4} + \frac{1}{\rho_2^4} \right) \right\} \quad \text{(B)}$$

but we have seen that $\frac{\delta}{\delta x}\frac{\delta^2\Omega}{\delta x^2}$ vanishes for some value of a/b between .5 and .71 so that $\frac{\delta^2\Omega}{\delta x^2}$ has a maximum between $a/b = .5$ and .71 for any ratio of c/b. Hence, $\delta^2 F/\delta x^2$ can always be made to vanish by taking a_1 and a_2 on both sides of the maximum. The values of $\frac{\delta^2\Omega}{\delta x^2}$ are graphically represented in figure 9, for $c/b = 1, 2, 3, \infty$.

At first these curves are in the order 1, 2, 3, &c., counting from above, but afterwards when they become distinctly asymptotic their order becomes reversed. This is indeed apparent from the equation.

An indefinite number of proper values for a_1 and a_2 may be got by the following simple construction. Draw any horizontal line cutting any particular curve in the points p, q; the x co-ordinates of these points at once give a special pair of suitable values, a_1 and a_2. In the case of simple coils, p and q coincide at the top of the curve, which is the case already discussed.

§ III. INTERNAL COILS FOR MEASURING LARGE DIFFERENCES OF POTENTIAL AND SMALL CURRENTS.

We are now in position to consider the dimensions which ought to be given to the internal coils spoken of in page 517 as necessary for the measurement of large differences of potential and small currents. For examining the above curves we see that $\delta^2\Omega/\delta x^2$ becomes very small when a/b is more than 3. Also putting (B) in the form

$$\frac{\delta^2\Omega}{\delta x^2} = \frac{\xi\,\eta\,\zeta}{\rho_0\,\rho_1^2}\left(\frac{1}{\rho_0^2}+\frac{2}{\rho_1}\right)+\frac{\xi\,\eta\,\zeta}{\rho_0\,\rho_2^2}\left(\frac{1}{\rho_0^2}+\frac{2}{\rho_2^2}\right)$$

and considering η and ζ as variables we may regard the action as due to two equivalent "electro-magnetic strips."* The coils are shown in the diagram below. There are four, one around each magnet. They are necessarily made of small height, in fact just enough to allow the wire magnets to move freely inside and yet to leave a good space for the jaw. For convenience of reference call these coils A, B, C, D, as indicated in the figure. From the symmetry of configuration we may take any one of the eight poles and consider the action of four coils upon it. Take one of the poles inside A and call it P_A for the sake of definiteness. The variations in the actions of C and D upon P_A, due to possible motions of the same, may be regarded as the differentials of the actions of electro-magnetic strips placed along the edges of C and D. These we may safely neglect in comparison with the variations in the actions of A and B. Thus we have only to consider the effect of the four faces of A and B. But since each coil extends a good way over the poles of the magnet, we may regard these coils as drawn out indefinitely in the direction of the magnets' axes without committing any sensible error as was shown in the last section. Hence, calling the distances of the faces of A and B from P_A, a_1, a_2, a_3, a_4, as in the diagram, we have

$$\Delta^2 F = \left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_1} + \left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_2} - \left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_3} + \left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_4} \quad \text{(C)}$$

where $a_4 = a_1 + a_2 + a_3$ from symmetry of arrangement. But from the curves given above we see that when a/b is more than 4, the values of $\frac{\delta^2\Omega}{\delta x^2}$ become insensible. Therefore by simply extending the ends of the coils so as to have the least value of a/b more than 4, we make $\Delta^2 F$ practically vanish.

* See my paper on the "Electro-magnetic Declinometer" published in the Proceedings of the Royal Society of Edinburgh (vol. xii. p. 544, 1883-4) or Rigakukyokwai Zassi (vol. ii, p. 84), in which curves are shown very similar to those just given.

Theoretically there is an indefinite number of solutions of the equation (C) obtained by selecting sets of values of a_1, a_2, a_3, a_4, such that

$$\left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_1} + \left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_2} + \left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_4} = \left(\frac{\delta^2\Omega}{\delta x^2}\right)_{a_3}$$

which is always possible since the curve has a maximum. But to apply such a mode of solution practically is dangerous on account of the steep rise of the curve toward the maximum. Any small errors in the values of a_1, a_2, &c., will give rise to an ultimate error greater than that caused by the neglect of the converging terms when a/b is made

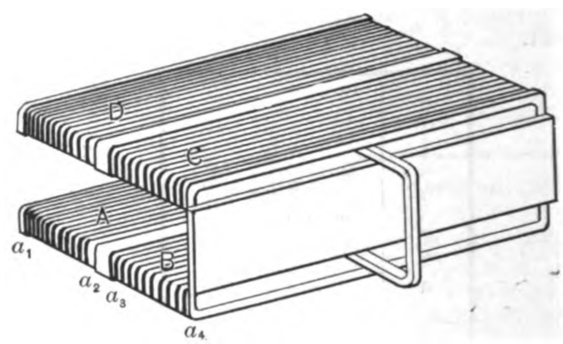

Fig. 10.

great. Hence, in practice it is advisable to make $a/b > 4$, and limit the range of deflection so that the least value of ξ/b should not fall within 2 or 3. If the instrument were constructed on a large scale with all the dimensions determined accurately, the graphical solution just indicated might be applicable.

Figure 10 above shows the actual coil belonging to the instrument represented in figure 4, which was purposely drawn without the coil so as to lay open its internal construction. Both these figures are drawn very nearly to full size. The central ridges which divide the upper and the lower coils into two parts serve for holding the pivots of the frame of the magnets.

The fittings of the levers and springs remain, of course, exactly the same as in figure 4.

The coil is wound with a thin copper wire in four layers and has a resistance of 40 ohms. An extra resistance of 5,000 ohms is added by introducing a small bobbin of fine german-silver wire (not shown in figure 1) into the back corner of the case of the instrument. The connection of the terminals is diagrammatically shown in figure 11.

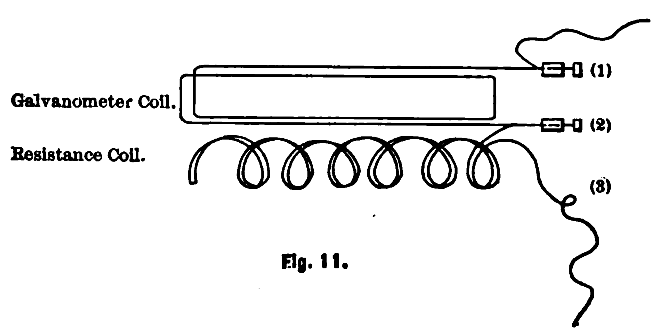

Fig. 11.

For the measurement of potential differences, the terminals (1) and (3) are used and for the measurement of small currents the terminals (1) and (2). To avoid the possibility of confusion as to which pair of terminals is to be used, a pair of binding screws are provided at (1) and (2) for the case of small currents, and a pair of wire ropes at (1) and (3) for the case of potential differences. An alternative construction would be to omit the pair of binding screws and provide a plug-hole between (2) and (3) to shunt off the resistance when the instrument is to be used for small currents. For the measurement of very

large potential differences or of moderate currents, a system of shunts may be employed in the usual way. Various other like devices may be multiplied almost endlessly.

A separate calibration is required for this coil, but this is nothing more than the ordinary galvanometer gauging. The following table gives a comparison of the readings of an actual instrument with those of a standard galvanometer:—

Standard galvanometer.		Pocket galvanometer.	
Reading.	Reduced to amperes.	Reading.	Value of 1 division in amperes.
7.8	.02278	25.8	.000883
13.6	.03971	45.1	.000880
22.1	.06453	73.2	.000882
		Mean	.000882

From the above result we easily find, for the given extra resistance of 5,000 ohms inserted, the value of the potential difference corresponding to 1 division of the scale. It is 4.4 volts (= .000882 × 5040). If a thinner wire be wound with a greater number of layers, it will be easy to make the above value 1 volt or less. Indeed this would have been done in the instrument now being described had it not been at the time impossible to obtain in this country a fine enough insulated copper wire. No doubt, the value required could be arrived at by simply reducing the resistance to little more than 1,000 ohms. This however would be too small for the purpose; if possible 10,000* ohms or more would be desirable.

§ IV. EXTERNAL COIL.

A single rectangular coil consisting of several hundred turns of a fine copper wire (see figure 12) may take the place of this internal coil just described, if one part of the coil be temporarily slipped in between the jaw in the same way as the so-called ribbon was slipped in when the instrument was being gauged. In simplicity of construction, this plan is perhaps superior to that of introducing the internal coil, especially when the instrument is to be made on a small scale. But it is inferior inasmuch as it needs an extra piece of apparatus.

Of course, we cannot regard this coil as equivalent to a single magnetic shell of an infinite extent. But referring to the diagram of the field of force given in figure 6, and the table of page 567, we see that the variation of the action of the coil due to deflections of the magnet will be insensible, if the height of the coil be such that the part outside the jaw is just below the base of the instrument, and if the length of the coil be such that the bends are distant from the nearest poles of the magnets by more than five times the distance between the magnets.

Further, we see that the part of the coil outside the jaw will add to the effect of the part inside by about 33 per cent., the current necessarily being in oppposite directions in these two parts.

The coil shown in figure 12 has 600 turns of copper wire and a resistance of 100 ohms.

Comparison with a standard galvanometer gave the following results:—

Standard galvanometer.		Pocket galvanometer.	
Reading.	Reduced to amperes.	Reading.	Value of 1 division in amperes.
11.8	.03446	41.2	.000836
17.4	.05081	61.0	.000833
21.2	.06190	74.5	.000831
		Mean	.000833

* Thomson's graded potential galvanometer has about 7,000 ohms.

Hence, when an extra resistance of 5,000 ohms is added 1 division of the scale will correspond to 4.25 volts (= .000833 × 5100).

Thus we see that the present instrument measures from .001 amperes to 168 amperes and from 4 volts to 400 volts, with a probable error of 1 per cent. The galvanometer

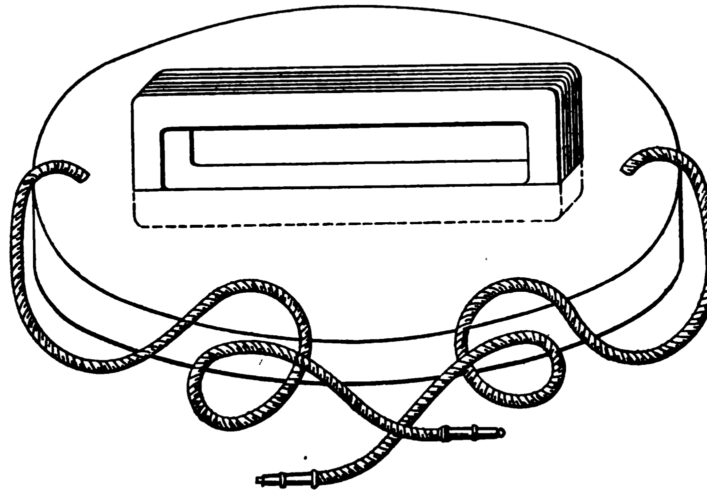

Fig. 12.

has, of course, three constants, one for the jaw, one for the internal coil, and one for the external coil if it has one. When these are once determined it is not necessary, however, to test all the three from time to time, since the ratios of the constants amongst themselves depend only upon the configuration of the instrument. These ratios being determined once for all, any change in the value of the constants, due to a change in the moments of the magnets or the strengths of springs, can be readily discovered by testing for any one of them, say, that for the internal coil.

PATENTS OUTSIDE THE COURTS.

BY GEORGE H. STOCKBRIDGE.

Is a patent a certificate of validity and value? If not, who is responsible? And how can the value of patent property be made more stable and certain?

An analysis of all adjudicated patents shows that seven out of every ten are sustained.[1] This settles the matter as to the *validity* of such patents as are brought to test in the courts. Moreover, it has been shown that the Patent Office is responsible for about two-thirds of the bad patents; and it has been suggested that a better showing, on the part of the Patent Office, would be made by bettering the conditions under which the work of the office is now done.[2]

In adding a final word to what has been said already, it is only fair to raise the question whether there are any considerations which affect the conclusions already drawn, or which serve to make the answers to our starting questions more complete. Are patents subjected to any tests outside the courts which affect their value as property? Or are the court records, for any reason, inconclusive as to the value of patents? This last point is exceedingly important as it touches a matter which is often overlooked, and yet which has everything to do with patents looked at from the standpoint of patent owners.

To begin with, then, the decisions of the courts serve to determine the one question of validity. Of course, if they deny that a patent is valid its fate is sealed once for all. But, on the other hand, a patent may be as strong as adamant, legally, and yet be a worthless piece of property, irrespective of the importance of the invention which it is

1. See the *Electrical World*, New York, April 30, 1887.
2. See the ELECTRICAL ENGINEER, October, 1888.

supposed to cover. Valid and valuable are two very different terms in the parlance of patents. A man may make an invention as important as the telephone and secure a valid patent on it, and yet hold a thing that would be dear at a quarter of a dollar, unless the parchment of the patent cover is at a premium.

To the initiated these things are already sufficiently familiar, but there are many others that ought to be initiated. The ordinary inventor holds that a patent issued on an invention is a patent which protects the invention, and it would be a good thing for him and for those with whom he deals, if they could learn the facts.

A patent which covers the mere structure, ingredients, or mode of operation set forth in the specification, generally represents money wasted. Every real invention is generic; that is, it represents an idea which is capable of different modes or forms of expression. And if my patent vests in me merely the exclusive right to the one form I have described, I have nothing of special value, unless, as may or may not happen, I have hit upon the only or the best practical embodiment of the idea. In making this statement I do not refer to new departures, like the phonograph, or the telephone, but I mean that this generic quality of invention extends to every detail and refinement of an art this side of perfection. In other words, every patentable invention is generic and may have a generic claim.

Now the courts are not called upon to decide whether a patent contains the broadest possible claim, but only to pass upon the claims actually contained in the patent document. Accordingly, it may easily happen that the records of an infringement proceeding will show that a patent was judicially sustained, whereas the scope of the patent may be so limited as to make it absolutely worthless.

But there is a tribunal which passes upon many such patents before they reach the courts. I allude to that class of cases which are adjudicated in lawyers' offices, and which never reach the courts at all. No one can do more than guess how large this class is, but my own recent experience and observation lead me to believe that it is larger than is usually supposed; certainly it is larger than I had supposed. In a patent practice of about four years' duration, some dozen of this class of patents have stuck in my own pigeon holes, that but for my advice, would be figuring in hopeless infringement suits. To that extent, then, the figures on the side of patents declared bad by judicial decision, have been reduced in a way that does not appear in the court records. Older attorneys must have contributed in far greater numbers to the reduction. There is a long list of patent attorneys, and, when the reports were all in, we might find a number of cases large enough to demand a considerable re-adjustment of our ratio of seven to three. How considerable, every one will have to estimate for himself. To some minds it will seem important enough to invalidate all conclusions based upon that ratio as a criterion for patents in general.

Now a patent lawyer or attorney who is called to pass upon patents in advance of the courts, finds just this difficulty most frequently; to wit, that the generic claim which ought to be there, is omitted. Sometimes these cases go beyond him, and, in spite of his advice, come up for a judgment in a higher tribunal. In a recent notable instance, familiar to electricians, a patent was thrown out in the courts because it did not cover the construction against which suit for infringement was brought. The inventor immediately applied to the Patent Office for a re-issue of his patent on the ground that he had intended to cover the construction referred to, but that, having been judicially informed that he had failed to cover it, he made application for a reissue to remedy the defect. By an oversight, the inventor in this instance secured his reissue; but how such reissue applications are treated generally, and properly, the public already knows.

A very common instance, however, is illustrated by the following: An inventor sees an unlicensed rival making and selling an invention which is a clear equivalent of one for which he has obtained a patent. "Bring suit," says he to his lawyer. "Well, but," "Well, but what?" urges the inventor. "The truth is, you have not got the claim you need for bringing suit." "But is not Smith making precisely what I invented and got a patent for?" "What you invented, certainly, but you unfortunately failed to obtain the claim that would have protected you." "Well, then, get me a reissue." "Let me see, this is November 22d, 1888, and your patent was issued November 23d, 1886. I am afraid we cannot get your reissue application into the office before the expiration of two years, and it will be of no use to apply for a reissue after that. Besides, a reissue with broadened claims stands little chance in the courts to-day." "But what have I done to forfeit my right to what I really invented?" "The courts say you have dedicated all but what you claim to the public. What you really did was to trust to an ignorant or incompetent or under-paid attorney. At least, I judge you had no actual intention of dedicating anything whatever to the public. But you have made a legal dedication and I cannot reclaim your property."

Here, now, is a deplorable state of things, and it is pertinent to ask, as before, who is responsible for it? If we can ascertain that, perhaps we can apply a corrective. And, doubtless, as before, the Patent Office, by ignorant or finical or obstinate rulings, contributes to the result. The main responsibility, however, is with the inventor or his attorney, and we who act in the latter capacity may as well take it upon ourselves. I have had occasion to remark, elsewhere, that a patent well drawn is a patent sustained. It may be added, here, that a patent well drawn is a generic, inclusive patent covering all the inventor has fairly invented and yet perfectly defensible in law. How few patents reach this standard not many of us would like to say.

From this point of view, it is easy to see that the judicial aspects of patents are, in themselves, among the least considerable to patent owners. The sustaining of a patent is of no use unless the patent itself is properly drawn. The best work (or the poorest) for the inventor is done by his solicitor, and not by his lawyers. Given a good patent, the labor of sustaining it is light; but a badly drawn patent is defeated already, if contested, and more than likely to be so worthless as to form no proper basis for a suit.

These are facts which it is proper that everybody should know. Were they more widely appreciated, they would exist less widely. In other words, the remedy would be applied, which, having gone thus far, I cannot omit to suggest. Inventors would employ intelligent attorneys and give them fees corresponding in some degree to the importance of the labors which they perform. So long as that is not the case, we shall continue to have the state of things set forth in the foregoing. The attorneys who are capable of giving legal opinions of weight will continue to shelve perhaps as many patents as the courts docket. With the prevailing fees, attorneys, no matter how intelligent, cannot do justice to their clients in patent cases. Every attorney knows this, and the best, or best established, of them come out openly and charge what their work is worth. There is a tendency upward in the fees of most of the best attorneys which the rest ought to uphold. It is the only way to improve the quality of patent work.

Under the British system, in the practical absence of rejections, the danger is that patents will be too broad. Before a patent is tested in the English courts, a solicitor commonly makes an exhaustive search (like one of our own validity searches mentioned above), for which, as is quite proper in view of the labor and responsibility involved, he charges a large fee. Under our system, the danger seems to be that the claims will be too narrow. Yet the decision of that point rests with the inventor's attorney, assuming that the examiner is competent and reasonable. But even under that assumption, what labor

is not involved in arguments, in compromises which shall not compromise, in appeals and petitions! All this can be so easily saved by concession, and yet concession means the loss of everything. It is true that an attorney who is conscientious or careful of his reputation will stand by, even if the pay be ridiculously small. But he will not choose to be caught a second time. The work of one of our attorneys is infinitely more important than that of those who make searches under the British system, for it involves the decision not only as to what form of claim is anticipated by the state of the art, but also what form can be sustained in view of it. The one creates the conditions by which the patent stands or falls, the other explores and reports on them. And yet what an insignificant sum the one receives, as compared with the other!

In a previous article, it was suggested that the way to improve the ratio of seven to three on adjudicated patents was to increase the room, force, and salaries in the Patent Office. To better the status of patents outside the courts, the patent fees, and consequently the time and labor devoted to each case, must be increased.

THE GEYER-BRISTOL METER FOR DIRECT AND ALTERNATING CURRENTS.[1]

BY PROFESSOR WILLIAM E. GEYER.

In the meter about to be described we make use of the heating effect of the current. Electric measuring instruments depending on this heat effect are not new. In the Cardew voltmeter we have an application which has found much favor. Here the current of greater or less strength traverses a long, thin wire, heats it more or less, and the direct expansion is a measure of the current, and indirectly of electromotive force.

In an ammeter it is necessary to keep down its resistance, and I therefore doubt whether direct expansion can be usefully applied for this purpose; for the actual elongation of a bar of metal even when raised through a considerable range of temperature is very small.

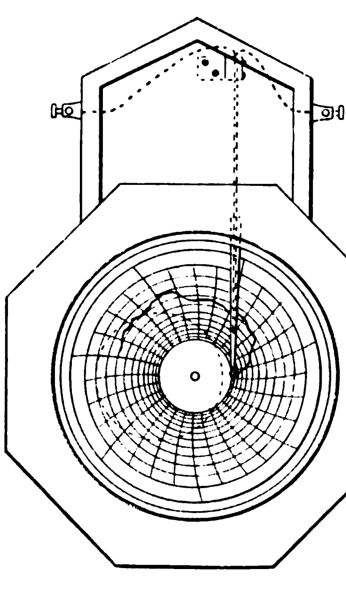

Fig. 1

In the familiar compound bar we have a case where a very small actual elongation produces a relatively very great lateral displacement.

I think I shall best be able to explain to you our meter, by recalling to your minds this old device. In the simplest compound bar two strips of metal which have different co-efficients of expansion are securely soldered flat wise along their entire length. Brass and steel are metals frequently taken. On heating, the brass expands more than the steel, and in consequence the bar bends, becoming convex on the side of the brass. When such a bar is heated by the passage of the electric current, it will deflect, and this deflection may be made a measure of the current. The disadvantage of such an instrument would be that atmospheric changes of temperature would also cause deflection, so that troublesome corrections would have to be introduced.

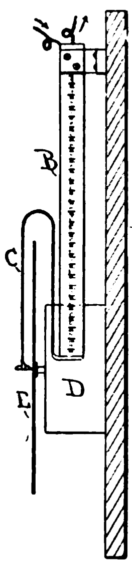

Fig. 2.

In our meter we also use a sort of compound bar, but eliminate at once the effect of surrounding temperature by taking metals whose co-efficients of expansion are the same or sensibly equal; in fact we take the same metal. Our first form of construction was as follows: A wire of german silver is laid upon a strip of german silver of considerably greater cross-section and radiating surface. The wire and strip are soldered together at one end, separated for the remainder of the length by a film of mica, then tie together at frequent intervals with silk or other insulating material, and suitably supported or clamped at the unsoldered end. If now a current, either continuous or alternating, is allowed to enter the strip at one end, it runs along its length, there enters the wire and leaves the instrument from the other end of the wire.

For a given current in the wire, on account of its greater resistance and also on account of its smaller radiating surface, the wire becomes hotter than the strip. In consequence of the difference of expansion, the bar bends, becoming convex on the side of the smaller conductor. This combination we call a differential bar.

We would also state that inasmuch as the results obtained by the use of this instrument are due to the excess of the heating effect of an electric current upon one portion of the bar or its equivalent over the other, it is in a measure immaterial to the principle of the invention whether the current which produces the differences in temperature be caused to heat the two parts directly or indirectly. For example, the more expansible part, in lieu of being included directly in the circuit, may be arranged in close proximity to, but insulated from, a wire or conductor which is heated by the current. The other part or element may be in the circuit or not; but in either case formed or arranged to be less sensibly heated than the other.

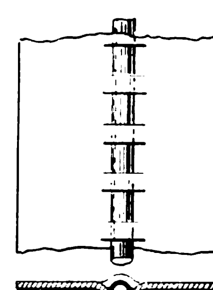

Fig. 3.

It will readily be seen, however, that to heat one or both of the parts of the device in this manner would be clearly equivalent to connecting them both in series in an electric circuit. Unlike the case where magnetic action is employed, the force here available is very considerable, so that to make the instrument self-recording it is only necessary to attach an inking device to the free end and move in front of it a properly ruled chart. In this respect we have no difficulty whatever. My associate, Professor Bristol, who has done the larger part of the work, has since our first experiments very much simplified the method of constructing the differential bar, and the one used in the instrument exhibited was made by placing a flat strip of german silver between a pair of dies which make alternate depressions and elevations along the length of the bar; the wire, insulated with asbestos was then slipped in the tube-like space thus formed, and the whole pressed between plates pro-

1. Read before the American Institute of Electrical Engineers, New York, November 13th, 1888.

vided with grooves of the proper depth, so as to leave the wire to one side of the centre line and at the same time to insure its being held firmly by the little bridges along the length of the bar. Since the bars can be constructed essentially by these two machine operations it is evident that they may be readily reproduced and at very small cost.

We have determined experimentally the best relation between the cross-section of the strip and wire to give maximum deflection. We believe the instrument could readily be made integrating but doubt the desirability of doing so. Our reason for this could probably not be better expressed than in the words of an eminent engineer, Mr. Charles E. Emery, in his paper on "Heating Cities by Steam," before the Franklin Institute, which we quote as follows :—

"It was at first considered unfortunate that a reliable meter could not be obtained, which, like a water meter, would show by differences of reading the quantity of steam used for the interval between observations directly without calculation, and without expense of maintaining a time register at each location, and of integrating the charts afterward. This system, however, proved a blessing in disguise. The greatest difficulty in settling with consumers lies in the fact that employés waste the steam. This is particularly the case during the heating season, when steam for various uses is left on continuously during nights and Sundays, thus increasing the time of consumption from, say, 60 hours a week to 168 hours. In many cases, too, the rate of consumption keeps uniform during the night as well as during the day, so that it is an easy matter to more than double the bills. The consumers at first naturally lay the blame to the steam of the steam company, but the meter charts have been the means of enabling the company to satisfy consumers when, and to what extent, the increased bills were due to mismanagement on their premises."

Substitute electricity for steam, the reasoning will apply perfectly to our case.

Figure 1 is a general view of the differential bar, mounted in a case with inker and recording dial.

Figure 2 is a side view of the important parts, the case being removed.

THE ABDANK MAGNETIC CALL AND THE ABDANK INTEGRAPH.[1]

BY B. ABDANK-ABAKANOWICZ.

PERMIT me to speak first of a small improvement in magnetic calls. The instrument that you see here, figures 1 and 2, was constructed as long ago as 1882, when calls for telephones were wanted everywhere. The principle of this call is extremely simple. For producing electromotive force we are obliged to move a coil through a magnetic field. I fix my coil at the end of a straight spring, the other end of which is solidly held by the support. On the same support are fixed two magnets that create the magnetic field. If I move the bobbin from its neutral position, thus bending the spring, I am storing up the muscular energy of my hand in the spring. If I remove my hand this energy is restored in a series of oscillations of the bobbin through the lines of force. In this way an oscillatory current is produced in the closed conductor, and the mechanical energy reappears on the other side in the form of the movements of the bell striker. I have made similar calls of different sizes, beginning with half the size of this one (about four inches), up to others where the diameter of the bell was three or four feet. As the electromotive force

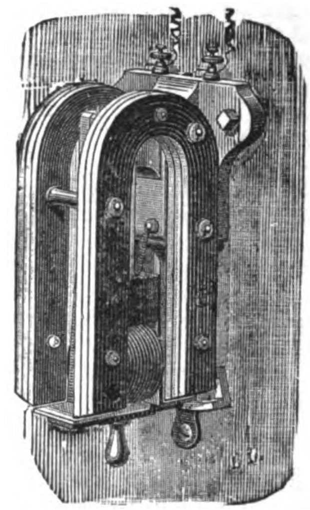

FIG. 1.

developed is very high the working distance is very great. This small one can ring a bell to a distance of over 100 miles over an ordinary telegraph wire. We have tried successfully larger calls on lines over 600 miles.

The apparatus is an old one, and I give the short description of it only as an introduction to some theoretical remarks on its working. In this country, calls approaching to mine, based on the synchronous movement, were patented by Andrews and Watson. Mr. E. Meylen has lately made measurements in my laboratory for the purpose of finding the curve of electromotive forces produced by the passage of the coil across the magnetic field, and this is the subject of my communication to-night.

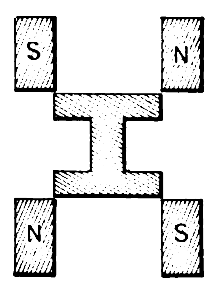

FIG. 2.

If we admit that the instrument is symmetrically constructed and that the magnetic fields are equal in strength, then the curve of induced electromotive forces must have a regular shape. We neglect also the retarding influence of eddy currents induced in the iron core.

We must have the greatest electromotive force in the middle, where the ratio of variation of the quantity of lines of force is the greatest.

The curve obtained by direct measurement was very different in shape, being as shown in figure 3.

This curve presents two remarkable features. First, we see a depression in the middle, where, theoretically, the electromotive force ought to be a maximum. The reason of this is to be found in the defective form of the iron core in the armature. The curves shown in figure 4 will clearly explain this.

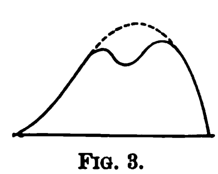

FIG. 3.

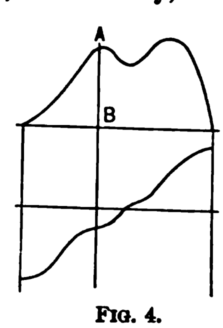

FIG. 4.

This defect in the construction has a very bad influence on the result, the greatest and most useful electromotive force being lost, as shown in the dotted line, figure 3, and the same defect was often found by me in different alternating current dynamos.

1. Read before the American Institute of Electrical Engineers, November 13th, 1888.

The second characteristic feature of the curve is in the shifting of its ordinates in the direction of the movement of the armature. Beginning from the starting point the curve is convex, and near to the other end concave in relation to the middle ordinate.

When the armature moves backward the same deformation was remarked, but in opposite direction.

The electromotive force produced was always somewhat behind the time in which it ought to have been produced. We supposed at first that this was due to the retardation in the indication of the electrometer used for the measurement, but we found by different controlling methods that this was not the case, and that this retardation is probably due to the action of eddy currents induced in the armature core. As you see, the maximum points of the curve are not symmetrically placed. This proves that the magnets did not possess the same strength of magnetic field.

The method used for the measurement of the ordinates of these curves was very simple.

The variation of the magnetic field in the path of the armature was also found experimentally, and then controlled by direct integration of the curve of electromotive force.

The ballistic method was used for the measurement. This method allows of the measurement of the variation of the quantity of lines of force independent of the time. The total variation of the magnetic flux was found to be :

$$\Sigma \, d \, F = 5.1 \times 10^7 \text{ (C. G. S.)}$$

The mean current was 0.021 ampere. The mean power was 0.26 watt.

The curve of the variation of the magnetic field can be found directly from the curve of E. M. F., as before alluded to.

Every ordinate of the curve of E. M. F. is proportional to the ratio of the variation of the number of lines of force.

It is equal to the differential coefficient $\frac{d F}{d x}$

Let us consider the four curves in their relation. Every ordinate, for instance A, B, figure 5, is proportional to the ratio of variation in the corresponding point of the second curve. This ratio is measured by the ratio $\frac{d y}{d x}$ where $d x$ represents time. The ordinate A, B, in a given scale, is equal to the numerical value of the differential coefficient. Every ordinate of the curve of E. M. F. represents the differential coefficient of the corresponding part of the magnetic curve. The magnetic curve is simply the integral of the E. M. F. It is obvious that if the equation of the E. M. F. were given, it would be possible to find the magnetic curve by integrating this equation.

This integration can be performed mechanically by an integrating machine. There is one of these machines constructed in Zurich, by the celebrated constructor, Coradi. To perform the integration it is sufficient to follow with the tracing point the given curve. The integral curve is then mechanically traced by the instrument. (M. Abdank here exhibited his integraph and explained its action.) The integration of differential equations is a problem that we meet continuously in the physical sciences. We perform an integration in determining the area of a given figure ; also in determining the static moments and the moments of inertia, in calculating the shape of the elastic curve.

The planimeter, as you know, gives mechanically the area and the moments. The instrument that you see before you gives much more. It traces a curve that indicates how the integral increases. The curve is the integral curve, the applications of which are extremely numerous. You have seen one of these applications for the determination of the magnetic curve.

I am glad to have had the opportunity to present it to this electrical society, and, as it were, smuggle into your presence a mathematical instrument under the cover of an electrical application. And I do so because the apparatus interests me personally, being myself the inventor of it.

I must also crave your pardon for having addressed you in English, of which language I am not at all a complete master, and I am ashamed, because that lack of knowledge is entirely contrary to my principles. I am of the opinion that every electrician ought to be able to speak English. He cannot be a good electrician without being a complete master of that language. Without an intimate acquaintance with the works of Faraday, he is not able to draw conclusions in a simple and logical manner from experiments. He cannot, without being in direct communication with the legion of workers in electricity who speak the English language and who have advanced electricity in this country to a point where it is 50 years ahead of that in Europe, I say, that without knowing it intimately, he cannot keep track of what can be done with that power of nature which we are all attempting to harness.

THE KEARNEY (NEB.) WATER POWER AND ELECTRIC DISTRIBUTION PLANT.

BY D. C. JACKSON.

To the casual observer who gains his impression of the Platte river from the windows of a car on the Union Pacific railway, it doubtless seems impossible that the broad but shallow stream with little water but much sand in its bed, can furnish a magnificent supply of water under high head to be utilized for power. It is a trite saying that Yankee ingenuity and engineering skill cannot be forstalled, and the Kearney water power is a good demonstration. The car window observer sees the water of the Platte apparently coaxed up hill so that in returning to the river from the top of the bluff with a fall of nearly 100 feet, it may turn the wheels of a rising manufacturing city.

The Platte river has an average fall of seven feet to the mile. Through a part of its course it is skirted by bluffs, which in places recede from the river for several miles and in other places run out and disappear. Breaking through these bluffs are "draws" or cuts caused by the erosion of many centurys' rainfall flowing from the country back of the bluffs to the river. At Kearney the bluffs are about two miles from the river on the north bank, and 17 miles up the river they run out. Here head gates are placed from which a canal, 20 feet wide and four feet deep, winds along the hillside for 17 miles to the top of the bluffs at Kearney. As the canal has been open only about nine months, but a small portion of the water is now utilized, the rest flowing over a weir into the tail race and thence to the river two miles south. In the 17 miles from head gates to Kearney, the river falls 119 feet and the canal 24 feet, giving a fall of 95 feet between the waste weir and the river. Of this, 15 feet is lost in the tail race and 80 feet may be utilized upon the wheels. At present the average depth of water on the water weir, which is 100 feet long, is nine inches, giving approximately 2,000 available horse-power. With the canal deepened and widened five times this power can be rendered available. The canal passes through a region in which no rock is encountered, hence enlarging it is a comparatively simple matter.

The shifting sands of the Platte river cause difficulty at the head gates by drifting in and filling the water passage to the canal. The highly interesting plan of a "rising basin" by the bank, but disconnected entirely from the river has therefore been the resort. Underlying central Nebraska is a gravel bed, through which flows a sheet of water which practically constitutes a portion of the Platte river and carries more water than the surface channel. The underground sheet has been tapped by a flume extending up stream along the river bank to a distance sufficient to gain a head from the underlying gravel. Though the works are

not yet completed, the success of the "basin" is practically demonstrated. When the basin is fully completed the canal will be supplied with water from a practically inexhaustible source, with which no expense will be entailed for annual repair of wash-outs, dams, and removal of sand bars.

In its course the canal crosses a number of "draws" which have been dammed, forming lakes (figure 1). These vary in area from 45 acres to 115 acres and in depth from 10 to 40 feet, thus serving as reservoirs of supply from which water may be drawn in cases of emergency.

It has been planned to place bulkheads at the Kearney end of the canal to serve as forebays, from which to conduct water to the wheels. One bulkhead is designed for the supply of three wheels, and one wheel has been set. The wheel is a 15 inch twin horizontal turbine set 40 feet below canal level, and fitted with draft tubes 20 feet long. Only 60 feet of the 80 feet head available is now utilized. Water is conveyed from the bulkhead to the wheel through a boiler iron tube 60 inches in diameter. The turbine develops 375 horse-power as now set, and runs at 550 revolutions per minute. The "twin" type of wheel gives an equalized pressure which makes the wheels capable of the severest duty, and the high head makes a power which is unequaled for steadiness under constant load. The high speed gives an advantage in belting direct to the dynamos of the transmission plant not equaled by the best high speed steam engine. In central Nebraska the cheapest soft coal, slack, coming from Wyoming, costs $3.75 per ton. In the eastern part of the state, Iowa slack coal of the cheapest grade costs about $2.00 per ton. The value of this prairie water power is evident. The population of the plains consume large quantities of manufactured articles made in eastern mills from raw products grown by themselves. Manufacturing has developed in the coal states east of the Missouri river, but is rendered impracticable through the cost of fuel, where steam is the source of power, in Nebraska, Kansas and Dakota. Kearney's location is such that there is every reason to believe the water power will make it a milling centre.

The topography about Kearney makes it inconvenient for manufactories to take power direct from the canal, and a distributing agent is required. The advantages of electric distribution of power over other methods have led to its adoption. The conditions require a plant covering a semi-circular area with a radius of about 8,000 feet, the power house being at the centre. The conditions of supply being that motors from the largest required down to those of one-eighth horse-power, and incandescent lamps be run from the same circuit. The large area calls for a high E. M. F. for satisfactory distribution, while on the other hand the lamps and small motors set a practical limit of about 220 volts E. M. F. To transmit large power at 220 volts several thousand feet is not to be considered on account of the cost of copper. The arrangement shown in figure 2 has been adopted as satisfactorily covering all conditions. Dynamos capable of producing 275 volts each, are driven two in series, giving a total possible pressure between the positive and negative wires of 550 volts at the dynamo; twenty per cent being lost on the line at full load gives at the lamps and motors 440 volts between the positive and negative wires, and 220 volts between the neutral wire and either positive or negative wire. Incandescent lamps of 110 volts are run two in series. Although certainly not advisable under ordinary circumstances, this is giving perfect satisfaction under the conditions at

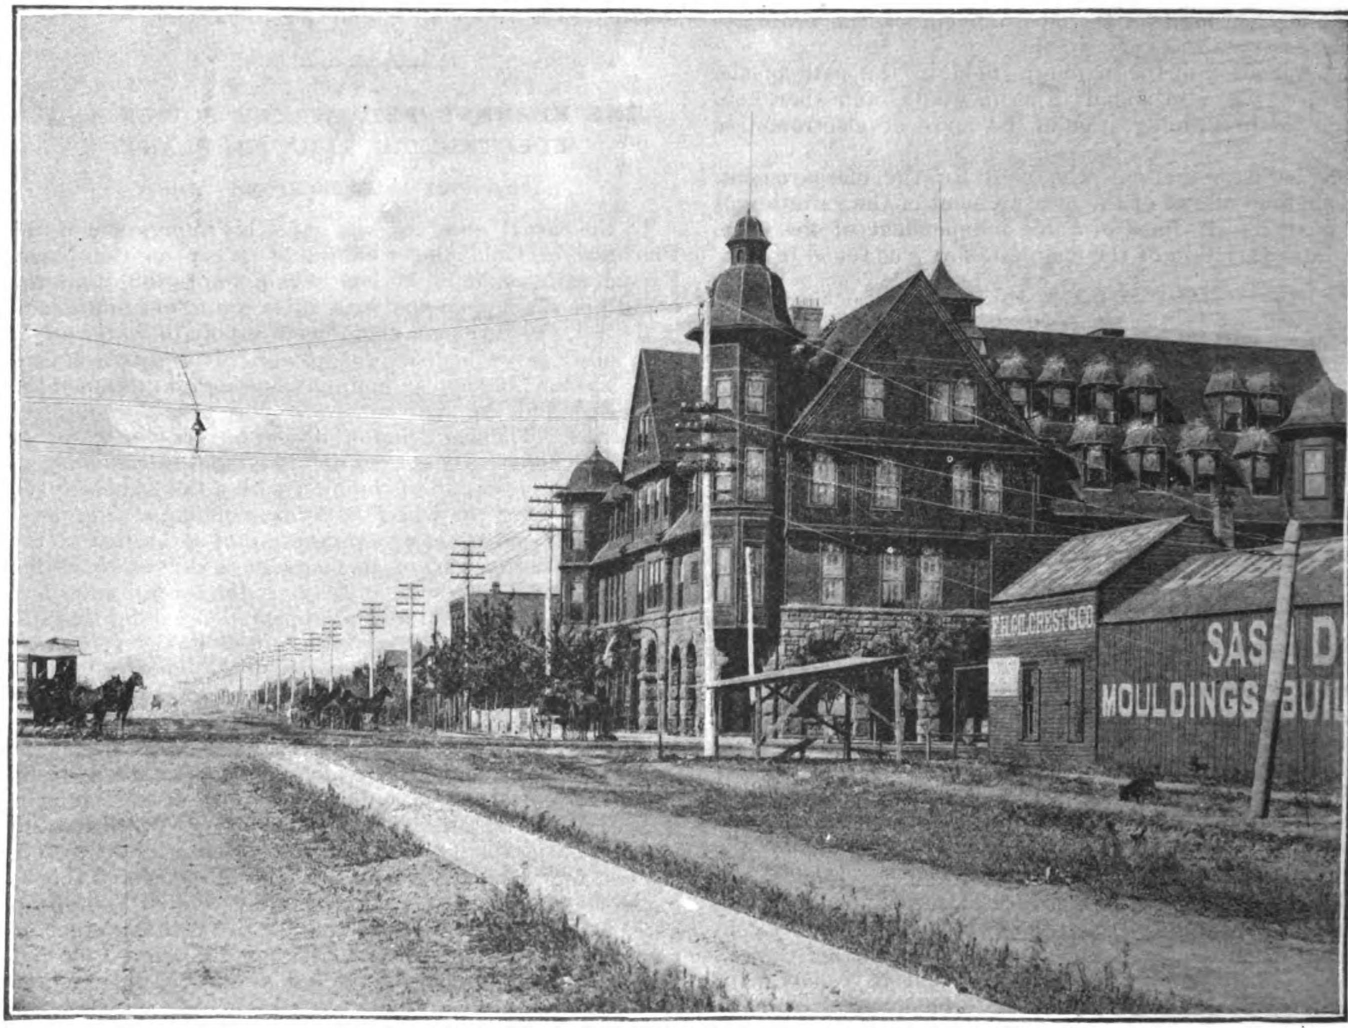

FIG. 3.—Pole Line. Electric Distribution Plant, Kearney, Neb.

Kearney. Motors of less than 5 h. p. are run under 220 volts, being placed between the neutral and positive or

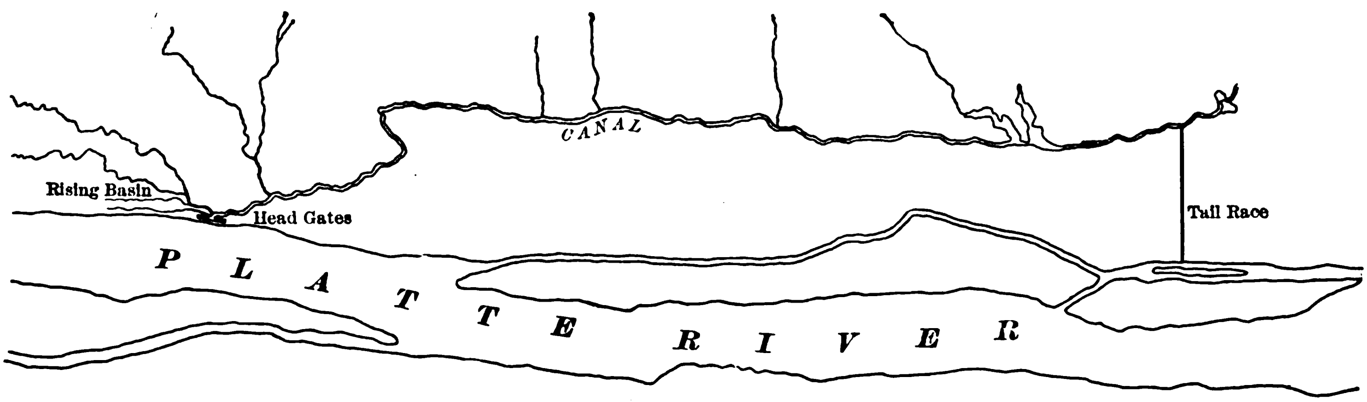

Fig. 1.

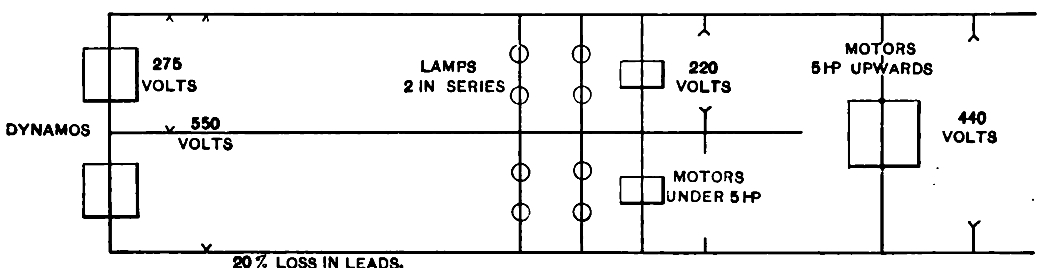

Fig. 2.

negative wire. Motors of 5 h. p. and upwards are connected from positive to negative wires and run under 440 volts. This grading of pressure makes it possible to run a small motor, driving a dental lathe for instance, as safely as a motor of many horse-power. As the plant is designed primarily for the distribution of power, with lighting of secondary importance, the usual methods of regulation of the three-wire system has been slightly departed from. The ordinary pressure indicators connected with load centres, and hand regulation are used, but feeder equalizers are not included. The sudden large variation of current due to large motors makes the effective use of equalizers practically impossible. The feeding points and network mains are therefore designed to keep a difference of potential within about two per cent. variation throughout the system under all loads. This is quite fully accomplished without an abnormal expenditure of copper, notwithstanding the apparent difficulty.

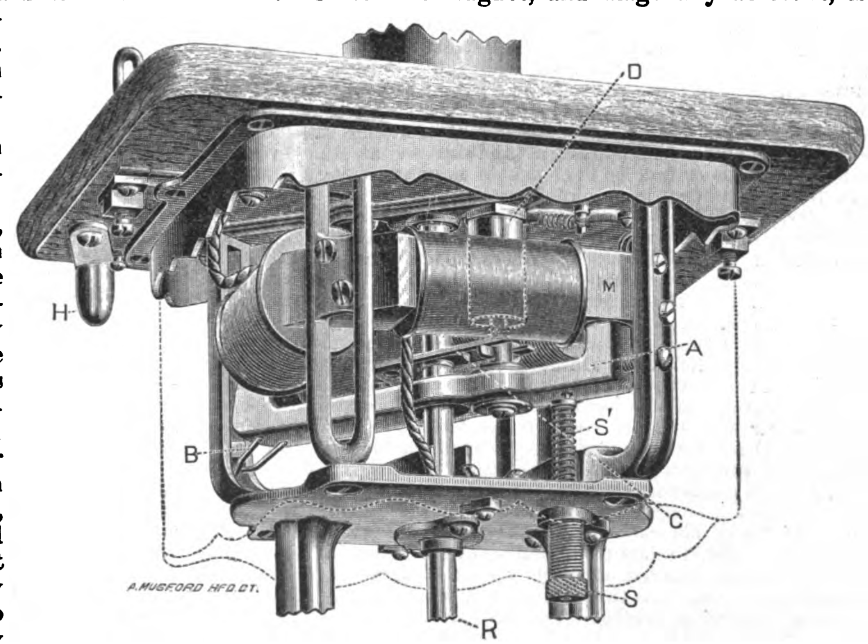
The plant throughout is constructed in the most substantial manner. Ample provision has been made against the two fiercest enemies of overhead wires in Nebraska, sleet and lightning. The dynamos used run at 1,100 revolutions per minute, and are equipped with journals automatically lubricated by the ring method. They easily stand the strain of 23 hours' work out of the 24, to which they are put. The large motors are also equipped with self-lubricating journals and small motors with metallic bearings. The line wire is all of a high test weather proof quality, and inside wiring is run upon porcelain knobs, making the insulation good, and rendering danger from leakage and grounds a minimum. As a whole, the plant is thoroughly provided for the severe duty of 24 hours' run per day from month to month, and power users are practically guaranteed uninterrupted service.

Figure 3 shows a portion of the pole line. A 2 h. p. motor is in service running printing presses. A 30 h. p. motor is employed in driving machinery in the brick works of Hunter and Frank, where a total of 50 h. p. capacity is placed. The motors above mentioned are located on the plant fully 8,000 feet apart "as the crow flies," one being 4,000 feet from the power house in one direction, and the other 7,000 feet in another direction. It is an interesting fact that this 30 h. p. motor is the first electric motor driven on regular power service from dynamos in Nebraska, and is the first motor used for driving brick machinery in the country.

LINCOLN, Neb., Nov. 12, 1888.

THE WATERHOUSE ARC LAMP.

THE Waterhouse arc lamp, illustrated below, has a magnet quadrangular in shape. Two independent conductors are wound upon it, the main being at right angles to the shunt. This produces two poles of constant polarity and two of variable polarity upon the magnet, and the variable poles are utilized in a manner subsequently described. Under the magnet, and diagonally across it, is



pivoted an armature, A, on one end of which is a tongue that protrudes into the elongated hole in magnet M. On the opposite end of armature A, and above supports B, the

armature is rounded and pivoted to the magnet M. While no current is passing through the lamps the pivot holds the armature in place while it rests upon supports B. The tongue end of the armature A is supported by S′. Attached to the armature is clutch C, which binds upon the carbon rod R. The spring S′ assists the armature to form the proper arc, and its tension is regulated by the screw S. Any sudden upward movement of the armature is opposed by the dash pot D, and any sudden downward movement by the spring S′.

The current entering the lamp at the terminal near handle H passes around the main coils, thence to the carbon rod and carbons, returning to the opposite terminal on the lamp board. This produces magnetism in magnet M. The armature A is drawn up, acting upon the clutch which lifts the carbon rod, and the arc is formed. On the burning away of the carbons the excess of resistance is greater in the main than in the shunt coils, and a portion of the current is diverted through the shunt, this neutralizes the magnetism in the variable poles of the magnet, as the shunt pole is an opposite one to the main. The neutralizing of the magnetism allows the armature A to recede slightly by gravitation, easing up on the clutch and releasing the carbon rod, which feeds the lamp. There is no sudden drop of the carbons, however, because the armature A is free from all mechanical friction and directly susceptible to the changes in the magnetism in magnet M. A fine steady feed will therefore be maintained.

An automatic cut-out (not shown in the illustration) is placed on the other side of the magnet, and will cut the lamp out on a quarter of an inch separation of the carbons.

The Waterhouse lamp is thoroughly insulated, is said to be easy of adjustment, and is made with clutch feed, as shown, or with rack and pinion feed.

ELECTROLYSIS OF TIN SALTS.[1]

BY ALEXANDER WATT.

(*Concluded from page 523.*)

4. *Tartrate of binoxide of tin.*—Bichlorate of tin solution was precipitated with a solution of sesqui-carbonate of ammonia, and the precipitate, after being well washed, was digested in a strong and hot solution of tartaric acid, in which the binoxide freely dissolved, forming a clear solution. The concentrated solution was next diluted with about eight volumes of water, and first tried with the current from a single Daniell, which, however, proved to be too weak, so a second cell was connected in series, when on immersing a clean brass plate an opalescent film of tin, of good color, and bright in parts, soon formed; but there was a vigorous evolution of gas at both electrodes. The film, though un-uniform, being in alternate streaks of bright and dull metal, was perfectly reguline, and there was no evidence of loose or spongy particles of metal after half an hour's immersion.

5. *Acetate of tin by electrolysis.*—A quantity of acetic acid, moderately diluted, was put into a glass vessel, and in this was suspended a tin anode and brass cathode, connected to two Daniells in series. In about a quarter of an hour the brass plate received a film of tin, at first white, but gradually assuming a dark-gray color. A single cell was next tried, when the deposit became whiter; there was a considerable evolution of hydrogen, the bubbles of which were of large size, before the plate became coated with tin, but as soon as the plate was covered with the deposited metal, the bubbles became considerably reduced in size, while the gas also escaped more freely from the tinned surface than from the brass. Indeed, the gas bubbles set free upon the naked brass rested for some length of time, until they attained the size of a small pea before rising to the surface of the liquor, whereas from the tinned surface they quickly escaped in small globules.

6. *Acetates of tin and soda.*—Sixty grains of acetate of soda crystals were added to about 10 ounces of the foregoing solution, and the mixture stirred until they were dissolved. A freshly prepared brass plate was then immersed, which slowly received a white and somewhat bright film of tin; this, however, gradually became dull and of a dark color. There was much gas given off at the cathode, which in about 15 minutes formed a thick, white froth on the surface of the liquid. The current from a single Daniell was used, and on examining the anode after a series of trials in this bath, the immersed surface was found to be very bright and clean.

7. *Nitromuriate of tin (dyers' spirit of tin).*—A solution of this salt was prepared as follows:—Sixty grains of sal-ammoniac were dissolved in one ounce of nitric acid, and to this mixture was added, in small quantities at a time, 60 grains of powdered tin. When the tin was all dissolved, the solution was gently evaporated, until a nearly solid mass was obtained, when the vessel was set aside until cold. The product, which formed a transparent, gummy mass, was next dissolved in about 10 ounces of cold water, and after filtration was subjected to electrolysis with the current from two Daniells in series. In this solution a brass plate received a dull but white film of tin—on the surface facing the anode only—after a few seconds' immersion. There was not much gas liberated at the cathode, but it was found that the anode became coated with a yellowish deposit, which, after a few minutes, assumed considerable thickness, while the solution acquired a yellow color, and finally became decomposed, when it ceased to yield a deposit of metallic tin.

8. *Sodio-bichloride of tin.*—Half a fluid ounce of the concentrated solution of bichloride of tin was added to 10 ounces (half-a-pint) of water. Sixty grains of chloride of sodium were then added and dissolved into the liquid, with stirring. The current from one Daniell cell was used, and a brass plate, as before, for the cathode. Immediately after immersion the plate received a good white deposit of tin, and deposition proceeded with perfect uniformity during a long immersion. When the plate was withdrawn the coating was found to be reguline, and there was no appearance whatever of sponginess at any part of the plate, while the anode was perfectly clean. A plate of steel was next put into the bath, and this became at once coated with tin, and at the end of half-an-hour or so received a fairly good deposit of the metal, which adhered well to the steel surface. It is probable that a solution of this composition, if prepared with care, might be found useful as a depositing bath, and since the anode becomes freely dissolved during the electrolysis, the solution would not be liable to vary much in its metallic strength. Another advantage which this solution presents is that only a very small anode surface—about one-fourth that of the cathode—is required. A solution that will coat brass and steel satisfactorily would also be applicable to copper and iron, and since a solution of this character is much needed, it may be worth trying on a larger scale than was necessary for the purposes of the foregoing experiment.

9. *Potassio-bichloride of tin.*—A dilute solution of the bichloride was first prepared, as before, and in 10 ounces of the liquid was dissolved 60 grains of chloride of potassium. The current from a single Daniell was used, and the immersed anode surface was about one-fourth that of the negative electrode, under which conditions, the latter, a clean brass plate, became coated with a pearly-white film of tin immediately after immersion; although the deposit somewhat darkened in color after a time there was no tendency to sponginess—or semi-crystalline character—while the deposited metal was firmly adherent. It may be said that there was little or no perceptible difference between the behavior of this solution and the preceding, but in some respects a preference might be given to the latter—if either could be found practically available.

10. *Ammonio-bichloride of tin.*—Half-a-pint of solution of bichloride of tin was prepared as before (experiment 8) and to this was added 60 grains of sal-ammoniac, in fine powder, and the liquid stirred until the latter was dissolved. The same current and anode surface were employed, when a clean brass plate became coated with a white film of tin immediately after immersion. There was but little evolution of hydrogen, and the deposition, as before, proceeded with perfect uniformity, there being no evidence of spongy metal during a prolonged immersion of the cathode. Although the results obtained from this bath were of a satisfactory character, so far as the metal having no tendency to sponginess, of the three solutions last treated I am still disposed to give the preference to the sodio-bichloride, that is assuming that either of them could be made available for the practical deposition of tin for useful purposes in the arts, which I am disposed to think is not beyond the region of probability.

11. *Tin chloride and pyrophosphate of soda.*—A moderately strong solution of pyrophosphate of soda was first prepared, to which was added gradually a solution of protochloride of tin, allowing the precipitate at first formed to redissolve before making further additions, the chloride solution being cautiously added until the liquid became nearly saturated. The solution was then set aside for an hour or so, and the clear liquor then decanted for use. The solution was then electrolyzed with the current from two Daniell cells, when a clean brass plate promptly received a white film of tin, which, however, soon turned gray, from the formation of spongy metal. The bath was next diluted with water, a little at a time, until the deposit retained its whiteness during a long immersion of the plate. This solution makes a very tolerable tinning bath, but since the anode dissolves but slowly, constant additions of the respective salts in a concentrated form are necessary to keep up the proper metallic strength of the bath.

1. From the *Telegraphic Journal and Electrical Review* (London).

The anode surface should also be much greater than that of the articles to be tinned in this solution.

12. *Sulphate of tin.*—A solution of this salt was prepared by dissolving recently-precipitated hydrate of protoxide of tin in hot dilute sulphuric acid. The solution was afterwards diluted with about 12 volumes of water, and electrolyzed with the current from a single Daniell, when a dull white deposit of tin at once appeared upon a brass cathode. After a short immersion the lower portion of the plate exhibited minute crystals of tin, which almost immediately after spread over its entire surface, and in a few minutes the crystals extended considerably, their growth being almost, if not actually, visible to the eye. The structure of the crystals from the sulphate solution was greatly different from those to which I called attention in the last paper, being of an arborescent or tree-like character; indeed, much like a leafless tree in winter. Some of these crystals were afterwards formed upon a glass plate, as described in the former article, but as they had a tendency to grow vertically as well as horizontally, they were not so well suited to print from by the photographic process as the chloride crystals; it is probable, however, that I may be able to overcome this little difficulty, and I hope to give an illustration of the sulphate crystals in the next paper, which I am anxious to do, as they differ greatly from the chloride crystals in structure. Being desirous of ascertaining whether further dilutions of the sulphate solution would tend to destroy its tendency to yield crystalline deposits, the bath was next weakened by the addition of an equal volume of water, and a fresh brass plate immersed, which promptly became coated with a white film of tin, and continued to retain its reguline character for some minutes, when the deposit gradually assumed the gray and spongy form.

From this and former results it appears that when solutions of tin, which in a more or less concentrated condition yield large crystalline deposits, the same solutions, when considerably diluted, cause the metal to assume a more minute form of crystallization, the agglomerated crystals taking the form of a spongy, but glittering mass. It was interesting to observe that the tin anode, after being used for some time in the several solutions named, acquired the peculiar crystalline appearance known as *moirée metallique*, and that it retained this character throughout a long series of experiments, although it had been considerably reduced in substance by the solvent action of the various electrolytes employed.

13. *Sulphates of tin and ammonia.*—A moderate quantity of sulphate of ammonia was added to the preceding solution and dissolved into the liquid with stirring. The bath was then tried with the current from a single Daniell, when a fine white film of tin was at first obtained upon a brass plate, but after a few minutes' immersion a spongy deposit appeared at the edges and corners of the plate The liquid was now again further diluted with water, and a very small portion of the anode only allowed to dip into the fluid, under which conditions a newly-prepared plate at once received a white coating of tin, and continued to do so without the appearance of spongy metal during the first five minutes, at the end of which time the corners of the plate again became coated with non-adherent and spongy tin. There was no gas evolved at the electrodes. A further dilution was next tried, at which point the solution had become exceedingly attenuated, with a view to obtain, if possible, a metallic deposit, free from sponginess—a reguline deposit, in fact. In the very dilute bath which resulted from the foregoing heavy dilutions, a brass plate now received a very white film, of a pearly hue, and for some time but little change was observable; eventually, however, the inevitable spongy deposit appeared at the bottom of the plate, when the experiment was terminated.

14. *Sulphate of tin by electrolysis.*—A dilute solution of sulphuric acid was first prepared, and in this was immersed a tin anode, connected with two Daniell cells in series, a clean brass plate, as before, being used as the cathode. In this solution, under the conditions given, the brass plate became thickly coated with spongy tin in less than five minutes, while a portion of the same deposit remained suspended from the bottom of the plate in the form of a thick spongy mass, which rapidly increased in bulk. The plate was now withdrawn, and the solution considerably diluted with water, a fresh plate being then immersed, which at once became coated with a white film of reguline metal; this character was not sustained, however, for shortly after the white layer became covered with a loose dark gray deposit of spongy tin. Further dilutions of the liquid were tried, but, as in all the previous trials with the sulphate solution, the deposit invariably assumed the semi-crystalline or spongy state soon after the first white film had been deposited.

15. *Persulphate of tin.*—A solution of this salt was formed by dissolving moist hydrated peroxide of tin in hot dilute sulphuric acid, the concentrated solution being afterwards diluted with about eight times its bulk of water, and filtered. In the solution thus prepared, and with the current from one Daniell cell, a brass plate quickly became coated with white tin, the film, however, gradually becoming rather dark in color after a short immersion. A good deal of gas was liberated at the cathode, and in a few minutes the deposit became of a dark gray color, this *secondary* film, as I may perhaps term it, being, as in all previous cases, non-adherent, while the first, or *primary* film, possessed all the characteristics of good reguline metal, from which the former could be removed by rubbing with the finger.

16. *Sulphates of tin and soda.*—A small quantity of a strong solution of sulphate of soda was added to a solution of tin sulphate, and the resulting liquid electrolyzed with the current from a single Daniell cell, when a white deposit of tin was at once obtained; this, however, soon became dark colored, and in a few minutes the plate was covered with a nearly black deposit of spongy tin. The solution was next weakened by the addition of an equal volume of water, when, on immersing a fresh plate, a pearly white film formed upon its surface, and retained this character for some minutes, when the spongy deposit began gradually to form and appeared in minute but separate lumps all over the plate, leaving the intermediate surfaces speckled, as it were, with the first white film, thus giving the plate a very singular appearance.

17. *Sulphates of tin and magnesia.*—Having frequently observed that an addition of sulphate of magnesia sometimes improved the character of metallic deposits from acid solutions, I added a small quantity of the magnesium salt to a solution of sulphate of tin, when I found that the deposits of the latter metal retained a reguline condition for a somewhat longer period than in some of the former instances, but the advantage was not long sustained, however, for the metal eventually assumed the spongy form; even when the solution was considerably diluted, the same result invariably presented itself, namely, the first layer of the metal after a certain time became coated with the semi-crystalline deposit.

18. *Sulphates of tin and potassa.*—A solution of the mixed salts in varying proportions, yielded results very similar to those above mentioned, and it was found to be practically impossible to keep the deposit in a reguline condition after the first film was obtained, unless the cathode was kept in constant motion, in which case the deposit retained its homogeneous character so long as the agitation was kept up.

19. *Chloride of tin and bitartrate of potassa.*—Sixty grains of cream of tartar were added to a moderately strong solution of protochloride of tin (7½ grains of the salt to each ounce of water) and dissolved into the liquor. The solution was then tried with the current from one Daniell, when a brass plate at once received a fine white deposit of tin, which retained its uniformly white color for several minutes, after which the plate gradually became dark in color, the spongy deposit appearing first at the edges and finally all over the plate. The solution was then diluted with about half its volume of water, and a new plate immersed, which, as before, received a brilliantly white film of tin, and continued to do so for several minutes, when the coating again darkened as before, from the formation of spongy metal, and at the end of about 20 minutes or so the spongy coating appeared all over the plate, but more especially so at the lower surface, where it thickened considerably, and eventually dropped off the plate in lumps. The solution was again diluted, and the experiment repeated, but although the deposition was exceedingly slow, a very small anode surface being immersed in the bath, the pearly white deposit at first obtained, as in the former results, was finally succeeded by the deposition of the metal in the spongy form.

In the last paper it was stated that there was some difficulty in obtaining tin crystals from sulphate of tin solutions, from which photographic prints could be produced direct, owing to the tendency of the crystals to grow vertically upon a flat surface as well as horizontally—a peculiarity which also occurs with some lead solutions, but notably with the nitrate of that metal. Wishing to reproduce crystals deposited from the sulphate of tin solution by the photographic printing process, if possible, I made some further attempts, and after a good many failures, succeeded in obtaining a few fairly good results. To form an electrolyte, half an ounce of sulphuric acid was added to eight ounces of water; this solution was poured into a flat dish, in which was laid a glass plate, 7 × 5 inches, the liquid being allowed to cover the plate to the depth of about one-eighth of an inch. A tin anode, connected to the positive pole of the two Daniells in series, was now laid on the plate, and the negative wire of the battery placed at a short distance from it. With this arrangement, a spongy deposit of tin appeared at the cathode in about 15 minutes; the anode was next shifted to about four inches from the cathode, the spongy metal having been previously removed from the end of the wire, when in a few minutes after the spongy deposit again appeared on the cathode. The anode was then brought within $\frac{1}{16}$th of an inch of the negative wire, and steadily held in that position, when a series of well-defined crystals immediately darted forward from the spongy mass, and were seen to move, with a wave-like motion, in the direction of the anode, when it was gradually drawn away from the cathode to prevent the deposited metal from coming in contact with the positive electrode. In the course of a minute or so, the delicate crystals, which were of a dark gray color, rose to the surface of the liquid, being buoyed up by bubbles of hydrogen which had collected beneath them, and thus the progress of the experiment was checked. The crystals were

now wiped off the end of the wire, which was then replaced, and, as before, brought as near as possible to the anode, without touching, when in a moment crystals again formed, but still more rapidly, and in about half a minute a deposit nearly an inch in length and three-fourths in width appeared, which, as before, rose to the surface of the liquid, and again temporarily suspended the operation. Having thus noticed that definite crystals could be

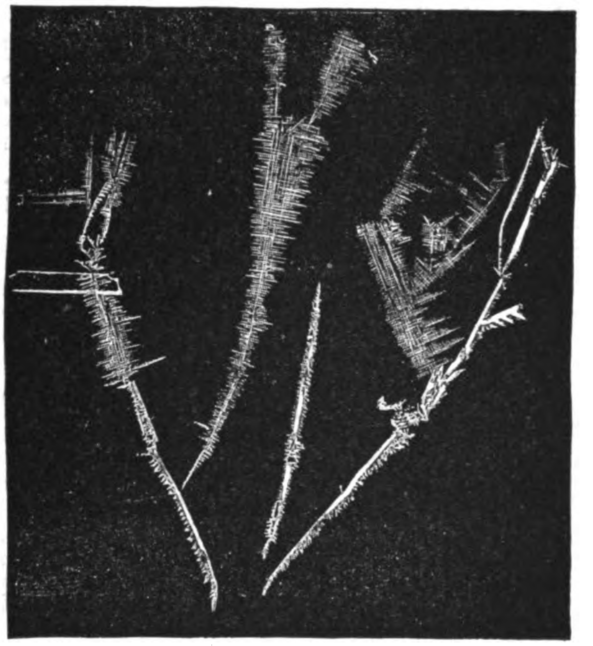


FIG. 7.

induced to spring out from the base of the spongy deposit, I next determined to strengthen the bath by adding a small quantity of a strong solution of sulphate of tin, in the hope of getting a group of crystals *beyond the spongy boundary*, without manipulating the anode in the manner described. To accomplish this, the electrodes were placed about five inches apart, and the bath left undisturbed for about two hours, by which time the following result was obtained: surrounding the negative wire there was a spongy

FIG. 8.

deposit of about one and one-half inch in diameter, from the extreme edge of which crystals, more or less well-defined, had grown, extending in all directions, but of course more especially in the direction of the anode. The result of this experiment is shown in figure 7, the black oval space at the base of the crystals indicating where the spongy mass was formed, and which it was found necessary to remove in order that the photographic paper might lie as close as possible to the crystals in the after process of printing from the plate.

In figures 8 and 9, are shown examples of crystals obtained from the sulphate solution previously described, the first of which (figure 8) was obtained with a wire cathode $\frac{1}{16}$th of an inch in section, and the second (figure 9) with stouter wire. In the three illustrations just referred to it will be seen how greatly the crystals obtained from the sulphate of tin solutions differ from those of the chloride, represented in the first paper of this series.

20. *Chlorides of tin and ammonium.*—A solution of protochloride of tin was first made, containing 7½ grains of the salt to each ounce of water. Sixty grains of powdered sal-ammoniac were then dissolved in 10 ounces of the solution, and the liquor

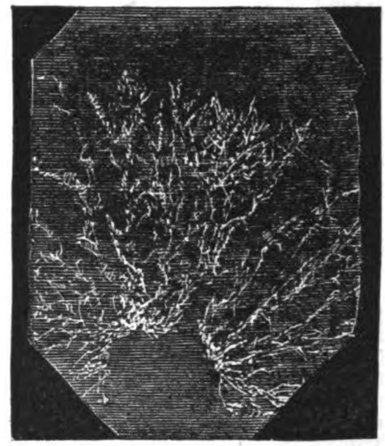

FIG. 9.

slightly acidified with hydrochloric acid. The bath thus formed was worked with a single Daniell cell, when a very prompt and white deposit of tin was obtained upon a brass plate, the anode surface being about one-sixth that of the negative plate. The film retained its whiteness, however, only for a few minutes, when the deposit gradually darkened and assumed the spongy or non-reguline form. The solution was next diluted with nearly an equal bulk of water, when deposition proceeded somewhat more favorably, and the metal retained its reguline character for a longer period than before; after a time, however, the surface of the plate beame coated with a pulverulent deposit, which was readily wiped off with the finger. The plate was then scoured with moist silver sand and returned to the bath, and was kept in constant motion for about 10 minutes, the anode surface having

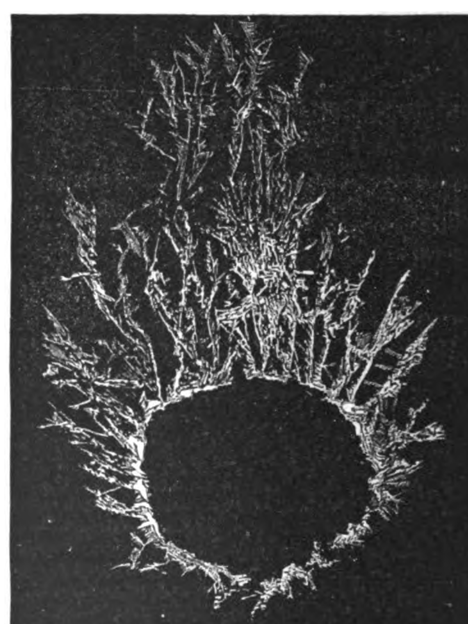

FIG. 10.

been somewhat increased, when it was found that the deposit was quite free from sponginess and perfectly reguline. The plate was again allowed to rest undisturbed in the bath for a few moments, when the coating soon assumed the gray and non-adherent variety of the metal. Another solution of the chlorides of tin and ammonium was next tried, in a somewhat more concentrated condition, when the metal at once deposited in the form of minute crystals, which covered the plate in a few seconds, while a group of crystals quickly started out from the edges of the plate, and in

about 15 minutes after nearly touched the anode, when they gradually drooped and sunk to the bottom of the vessel, where they accumulated with great rapidity, forming a glistening cluster of great brilliancy. This experiment verified what had been before noticed—namely, that the weaker solutions yield smaller crystals of the metal, forming a spongy mass, while they assume larger dimensions and more definite forms in liquids richer in metal. In figure 10 an example is shown of crystals obtained in the stronger bath of the composition given, in which it will be observed that a new crop of crystals appears to grow out of the truncated apex of the upper group of crystals—those which were nearest to the anode. I have found that the growth of these crystals can be considerably modified by altering the position of the electrodes; for example, if the crystals are allowed to approach the anode until they nearly touch this electrode, they invariably assume a flattened appearance, or as if they had been cut off at these points; if now the anode be drawn away from the crystals to the extent of an inch or two, in a few moments after we shall observe that a fresh growth will spring out from the truncated crystals, and, in some cases, these will be of an entirely different character to those of the original group.

21. *Tartrate of Tin.*—A bath was prepared by digesting moist carbonate of tin in a strong and hot solution of tartaric acid, the resulting liquid being afterwards filtered and moderately diluted. With the current from a single Daniell cell a bright and very white deposit of tin was at first obtained, but this gradually turned dull, and after a few minutes' immersion of the plate the deposit was found to be powdery and non-adherent. The metal, however, was readily obtained in the reguline form, and perfectly white, by keeping the cathode in motion while deposition was progressing.

22. *Oxalate of tin.*—A solution of this salt was formed by digesting moist hydrated protoxide of tin in a hot and strong solution of oxalic acid, the liquid being afterwards filtered and moderately diluted. With the current from a single cell a brass cathode received a prompt deposit of tin from this bath, the immersed anode surface being somewhat larger than that of the negative electrode. The deposited metal was of a good white color, though dull, and perfectly reguline.

23. *Peroxalate of tin.*—To prepare a solution of this salt, a quantity of moist hydrated peroxide of tin was digested in a hot solution of oxalic acid, and the clear liquid when cold was sparingly diluted and electrolyzed with a single Daniell, when a brass plate received a coating of tin, but not of a very good color, a few seconds after immersion. The deposit was somewhat irregular and patchy, but otherwise perfectly reguline.

24. *Borate of tin.*—Although this salt usually occurs in the form of an insoluble powder, a small percentage of the hydrated protoxide, or of the carbonate of tin, becomes dissolved in a nearly boiling solution of boracic acid, and the resulting liquid, electrolyzed with one or two Daniells, yields a deposit of metallic tin upon a brass cathode. Beyond this fact, there is nothing of interest in the electrolysis of this solution.

25. *Nitrate of tin*—A solution of this salt was formed by digesting recently precipitated and moist hydrated protoxide of tin in dilute nitric acid, the liquid being afterwards filtered and diluted with water. When electrolyzed with the current from a single cell, a film of tin was received upon a brass plate soon after immersion, but shortly after a yellow deposit formed on the plate, while the anode became somewhat thickly coated with a white insoluble substance—probably a basic salt. The solution being nearly neutral, a few drops of nitric acid were added, and a fresh plate immersed, when a bright and very white film of tin was obtained on a brass plate; this, however, soon became dull, and a yellowish film again formed on the face of the cathode and reguline metal ceased to deposit. It was noticed that in this solution the anode entirely lost the crystalline appearance which it retained in almost all the other solutions tried, while a somewhat firmly adherent and perfectly white salt coated the anode, giving it the appearance of enamel.

26. *Pernitrate of tin.*—Recently precipitated peroxide of tin was digested in dilute nitric acid, and it was observed that the oxide was more freely soluble in a weak than in a strong solution of the acid. A nearly neutral solution of the persalt having been obtained, the current from a single Daniell was passed through it, when it at once became apparent that the liquid became decomposed, a brownish-yellow deposit having formed upon the anode, which rapidly dissolved in the liquid, imparting to it a yellow color. There was no metallic deposit upon the cathode, but a white gelatinous mass formed upon its surface; the bath was now allowed to rest undisturbed for several hours, at the end of which time it was found to have assumed a very peculiar appearance: surrounding the anode, and projecting beyond it to the extent of several inches, a profuse light brown mass had formed, while the whole of the liquid beyond this boundary had been converted into a white gelatinous mass—the contrast between the substances formed at the anode and the cathode respectively being exceedingly marked. On examining the cathode at the conclusion of the experiment, it was found to be very slightly coated with tin of a dark gray color, while beneath the light brown deposit formed at the anode there was found an opaque white stratum, which came away from the plate in hard flakes when scraped with the finger nail. On removing this layer, the underlying surface of the anode presented a brilliantly white appearance, but quite free from the characteristic crystalline appearance which tin invariably assumes when electrolyzed in either acid or alkaline liquids. It thus appears that no less than three different forms of tin are produced during the electrolysis of the pernitrate of that metal, two of which, one of a light brown color and the other white, are formed at the anode, while the remainder of the liquid becomes nearly solid from the formation of a white gelatinous matter, probably a basic salt. It seems difficult to account for the presence of two different deposits at the surface of the anode, but more especially for the light brown color of the deposit overlapping the white layer, which latter was closely attached to the surface of that electrode.

27. *Ferrocyanide of tin in caustic potassa.*—A bath was prepared from this combination as follows:—A solution of ferrocyanide of potassium was added to another of protochloride of tin until the whole of the metal was precipitated as ferrocyanide, which was then filtered and washed in the usual way. The resulting mass was next dissolved in a tolerably strong solution of caustic potash, and the liquid afterwards considerably diluted with water. The bath thus formed was tried with the current from a single Daniell cell, when a prompt and pearly-white film of tin was at once received upon a brass plate, the electrode surfaces being about equal. It should be mentioned that before the bath was put into good working order, increasing proportions of water required to be added, until the solution had become exceedingly weak, in which condition it yielded very satisfactory results, while the anode kept perfectly clean. A clean plate of iron was next placed in the solution, but it was found to become coated so slowly that a second cell was connected, when the iron surface quickly became coated with tin. It is probable that a tinning solution prepared from the above combination might be found useful, and if so it would also have the advantage of being cheaper than some of the baths which have been employed for electro-tinning.

28. *Ferrocyanide of tin in cyanide of potassium.*—A solution was prepared as above, substituting a strong solution of cyanide of potassium for the caustic potash, but the solvent action of the cyanide is so far inferior to that of potash, that its employment cannot in any degree be recommended. Although tin can be deposited from the double cyanide solution of a pearly whiteness, a bath of this composition would be of no service for practical purposes.

29. *Cyanide of tin.*—The hydrated oxides and carbonate of tin are so feebly attacked by even very strong solutions of cyanide of potassium, that we may say that tin solution prepared with the cyanide would be absolutely useless for the deposition of the metal.

30. *Peracetate of tin.*—Having noticed the peculiar behavior of the pernitrate of tin under electrolysis, it was determined to see what results would be obtained with the peracetate, for which purpose a small quantity of solution was prepared by digesting moist hydrated peroxide in a strong solution of acetic acid, moderately heated. The resulting liquid, after filtration, was tried with the current from two Daniells, when a white film of tin slowly formed upon a brass cathode, the deposit eventually assuming a dark gray color. There was a rather brisk evolution of hydrogen, and no non-metallic product formed at either electrode.

In the foregoing experiments, while ascertaining the behavior of various tin salts under electrolytic action, I was also desirous, if possible, to discover some preparation of tin which would be less open to objection than the salts ordinarily applied for depositing the metal, and if I have not succeeded in securing a formula for an absolutely reliable tinning bath, it is possible that some of the results given may be worth further attention at the hands of those who are specially interested in the electro-deposition of tin for commercial purposes.

LIGHTNING.[1]

BY S. A. VARLEY.

(Concluded from page 527.)

Let us now assume the hydraulic view of the transmission of electrical energy to be the more correct one. A suspended conductor may then be regarded as a **U**-pipe full of water. What would happen if water in a rapid state of motion be propelled against one of the mouths of this **U**-pipe. The inertia of the stationary water would effectually prevent sudden transmission through the pipe, and the consequence would be that the potential of the propelled water at the point of impact would be increased in a similar manner to what occurs in a water ram, or

1. From the *Telegraphic Journal and Electrical Review* (London).

what is observed when a hard metal block is struck by an equally hard hammer; the force developed in an infinitely small space would be infinitely great, and the propelled water would either rebound or scatter itself horizontally.

Now I am disposed to believe we have here an explanation of what was observed in the alternative path experiments. When discharge occurs something must give way, and if the B balls be separated beyond a certain distance, the discharge cannot occur in their immediate neighborhood, and as the conductor forming the alternative path, as a consequence of its magnetic inertia, opposes so great a resistance to longitudinal transmission, lateral discharge in a greater or less degree occurs in the air space separating either sides of the alternative path conductor, and also in some degree from it to the walls of the room; and I venture to think if the experiments recorded had been performed in a darkened room, luminous stars would have been observed on the surface of the loop conductor at the moment of discharge, and chiefly at the positive end of the loop.

What I now suggest affords, I think, an intelligible explanation of what was actually observed; the B spark is in all cases produced as a consequence of the magnetic inertia of the alternative path conductor, and if such conductor be an iron one, possessing greater inertia than copper, then the tendency for lateral sparks from such conductor will be greater, and the finer the wire the more readily will lateral discharge occur between the alternative path and the walls of the room. In fact, there would be created a third or C space through which part of the electrical energy dissipates itself, and it must not be overlooked that the walls of the room under such conditions become the two coatings of a Leyden arrangement, and by permitting the accumulation of a statical charge introduce the element of time.

In reference to the behavior of the lightning discharge which struck the vane rod of Doncaster Church, and the phenomena which have come under my own observation, where telegraph circuits having multiple protectors have been struck, I have suggested by way of explanation that something of the nature of momentum is produced by the electrical motion set up in the atoms composing the conductor. I do not wish it to be considered that the explanation attempted is other than a mere suggestion.

What occurred at St. George's, Leicester, and Doncaster Church can be explained by Professor Lodge's alternative path experiments, but that described in reference to multiple protectors cannot, I consider, be so explained. What there takes place is very suggestive of an actual blow being struck, and resembles what occurs when a metal rod receives a sudden mechanical impact.

If a metal rod, A, A[1], figure 7, be mounted on a stand, S, firmly fixed to a bench to prevent longitudinal motion, and a ball, B, suspended by a string rests against the end of the rod at A[1], if a sharp blow from a light hammer be given to the rod in the

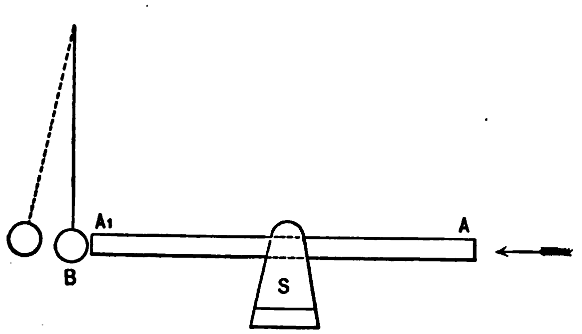

Fig. 7.

direction shown by the arrow at A, the ball will be propelled as indicated by the dotted lines. A similar result may be produced by simply rubbing the rod in the neighborhood of A, so as to throw the molecules into a state of vibration.

Now, whatever may be the cause of the appearance of electrical momentum, the preference manifested by lightning for a straight course when passing through a conductor makes it difficult to my mind to comprehend an electrical discharge leaving a longitudinal path when there is a clear road through it to the earth; but this is what Professor Lodge seems to think does happen, and he attributes it to oscillations and the surging of electric discharges in the lightning conductor, for he says in the first of his two lectures:—"If the earth is bad, the flash can show its displeasure when it gets there by tossing it about, and boring holes into it, and breaking water and gas mains; but at least it might leave the top and middle of the chimney alone, it might wait till it got to the badly conducting place before doing the damage. Yet it is notorious that on high chimneys a flash often refuses to follow a thoroughly good conductor more than a quarter or half way down, but takes every opportunity of jumping out of it and doing damage. Why is this? Well, that is the main question I shall attempt to answer in this course."

I must differ from Professor Lodge when he says:—"If the earth is bad the lightning can show its displeasure when it gets there by tossing it about, etc." Dessicated earth and dessicated wood are good insulators; both owe any conducting properties they may possess to moisture associated with them; this moisture is an electrolytic conductor, and the finely divided water particles become polarized by a sudden discharge, developing, then, enormous resistance. What I have just stated I may, by the way of parenthesis, say incidentally explains the two-fold behavior of the wood table on which the jars rest in the "alternative path experiments." Wood allows of slow conduction to electric currents of any potential, and therefore the charging of the jars was not seriously impeded, but to a sudden discharge the wood becomes practically a perfect insulator, and the discharge consequently leaps a considerable air space in preference to passing through the wood.

We are familiar with two examples of oscillations, viz., the pendulum and the spring; in both cases matter is being acted upon by force, the oscillations being solely due to the fact that matter possesses weight and inertia. Inertia, as stated in an earlier portion of this article, I am disposed to regard as a storage of force. Weight represents the amount of inertia possessed by matter, and rate of motion, it seems to me, expresses the quantity of force stored up in the moving body; for example, four times the force must be expended to give a rifle ball twice the initial velocity of another one; two parts of this force would appear to be imparted directly as velocity, and the other two parts to be stored inside the ball; and, consequently, if the ball be projected vertically it resists the action of gravity for twice the time and travels through four times the space.

I have gone into this subject somewhat at length, because I wish to emphasize the fact that oscillation involves matter. I think it would hardly be too much to say all oscillation we are familiar with are a consequence of a storage of force in matter; if we assume this to be so, would it be too much to suggest that if there be such a thing as electrical oscillation, that matter must be concerned in such oscillation.

Professor Lodge does not seem to doubt the existence of electric oscillations, and he conjectures many millions of oscillations occur in the space of a second in the case of a lightning discharge, consequently it may be considered impossible for their existence to be occularly demonstrated.

Let us, therefore, consider a Leyden arrangement whose rate of discharge is not so rapid. Take, for example, a long submarine cable statically charged to a high potential, it will be found to discharge itself in a precisely similar manner to water through a pipe inserted into the bottom of a reservoir of water where the rate of flow would be determined by the height of the column, and the diameter of the pipe and this rate of flow would decrease as the height of the column of water in the reservoir decreased, there would be no such thing as oscillation under the conditions I have described, but if the discharge pipe were a long one, and if it were elastic it would become distended by the pressure to which it was subjected, and as the pressure became less the spring of the pipe would react forcing back the water, and in this way oscillations might be set up.

Let us now consider what would occur if a charged condenser be connected through a long conductor to second condenser which is not charged, the electricity would rush out of No. 1 condenser through the conductor into No. 2 condenser; the rate of flow in the first instance being determined by the potential to which No. 1 had been charged, and such rate of flow would decrease directly as the potential became lowered by discharge. The magnetic inertia of the conductor would cause a certain amount of obstruction which would have to be overcome; in other words, energy would be stored up in the form of magnetism, and as the potential of No. 1 condenser became lowered, this stored up energy would be given out and the effect would be to continue and prolong the flow into No. 2 condenser, the potential of whose statical charge would thus become raised to a higher degree than that of No. 1 condenser. When this point has been reached a reaction would occur and the electricity would flow now from No. 2 condenser back again into No. 1. The reversal in the direction of the flow involves magnetizing the conductor in the opposite direction, storing up energy again (in a less degree to that previously described) and prolonging the flow into No. 1 condenser. In some such way as just explained it is, I think, conceivable that oscillations may be set up in a conductor, and granted this be so, my contention is that any electrical oscillation which may occur must be set up by some action in the conductor itself; and the only source from which they can proceed, as far as I am able to see, is the magnetic inertia of the conductor. Now if this be the source of such oscillations, then the discharge must take place through the interior of the conductor and not pass over the outside, as Professor Lodge seems to consider to have been "abundantly" demonstrated.

I may remark, by the way, that although the existence of oscillations are taken for granted, there is no suggestion in Professor Lodge's lectures how the oscillations are produced.

Oscillations in a lightning conductor involve the assumption that the earth acts as a condenser and not as a conductor; and

assuming such oscillations do occur, they must be a consequence of the magnetic inertia of the lightning conductor, they can hardly be considered to be produced in the air space separating the clouds from the earth, for if they were developed here the oscillations would be confined to the air space, the lightning conductor and the earth, and they would not surge about through brick walls to conducting matter in the interior of protected buildings, as suggested by Professor Lodge.

I wish to put the matter as fairly as I can. I am no partisan, but simply a student anxious to arrive at the truth whatever it may be. If there be oscillations they must have their origin in some source, and if they rebound from the earth one cannot easily conceive their surging about and reaching the earth through a different channel to that in which they occur. For my own part, regarding the earth as I do as a conductor, I cannot imagine when there exists a good connection between it and the lightning conductor, such a thing as oscillations being set up in the lightning conductor.

During the serial publication of this paper my attention has been directed to some essentially practical lightning conductor experiments published in a contemporary and carried out for them by Mr. Wimshurst. The outcome of these experiments (to quote the words of your contemporary) is to restore confidence in the ordinary lightning conductor.

I am pleased to find the experiments I am now referring to harmonize generally with the conclusions stated in this article as having been arrived at from what I regard as common sense reasoning.

The first set of experiments were made with conductors of copper, and iron wire, copper and iron riband, and iron wire enclosed in a thin copper tube, as below :—

No. 1.	No. 14 B. W. G.		copper wire.
" 2.	"	"	iron wire.
" 3.	"	"	copper riband.
" 4.	"	"	iron riband.
" 5.	"	"	14 iron wire enclosed in copper tube.

The above five conductors were mounted horizontally on glass supports, and placed between two vertical metal plates, one of which represented the cloud and the other the earth. One end of each of the conductors rested against the earth plate, and an air space, the length of which was varied in the course of the experiments, divided the other ends of the conductors from the cloud plate.

The arrangement of the Leyden jars, in respect to the earth and cloud plates, was precisely similar to that of the "impulsive rush" experiment of Professor Lodge, shown at figure 8, the only difference being that the two balls and the pointed conductor shown in the figure were replaced by the five conductors of equal length.

The air space dividing the cloud from the conductors was in the first set of experiments one inch, and this was gradually increased to five inches. At each stage the charged Leyden jars were discharged from the cloud through the air space, the particular rod selected by the electrical spark being noted.

The following results are given as having been obtained when the air space was three inches :—

The copper rod was selected	6	times.
" iron " "	5	"
" copper strip "	5	"
" iron " "	3	"
" copper covered iron was selected	2	"

The distance between the ends of the rods and the cloud was then increased to four inches, and the results obtained were :—

The copper rod was selected	4	times.
" iron " "	2	"
" copper strip "	13	"
" iron " "	3	"
" copper covered rod was selected	2	"

With a five inch air space the results were :—

The copper rod was selected	13	times.
" iron " "	5	"
" copper strip "	0	"
" iron " "	2	"
" copper covered iron was selected	2	"

It is stated that in reference to the above experiments it was considered it would be "unwarranted to draw any conclusions except that the course of the discharge is determined mainly by atmospheric conditions, and that a metallic conductor, if it be of sufficient size to carry the current without destruction, may be of iron or copper, round or flat, as may be most convenient. If we attempt to reckon up the totals of the three experiments, we find that the copper rod shows the best score, and the copper strip the next best; but a comparison of the behavior of the copper strip in the second and third experiments shows that this method of estimation is very risky." To test the action of a bad connection between a lightning conductor and the earth, four other experiments were tried, in which there was an air space between the ends of the conductor and the plate representing the earth, as well as between the conductors and the cloud, and 81 discharges were passed. The following are given as the aggregate results of the four experiments :—

The copper rod was selected	11	times.
" iron " "	20	"
" copper strip "	20	"
" iron " "	13	"
" copper covered iron was selected	17	"

The following remark is made in reference to above experiments : "If we attempt to draw any conclusion, it is that an iron rod and a copper strip stand on an equality, but an examination of the detailed results, which are too long to be given here, shows that the selection was very erratic. One rod would be struck several times in succession, and then would be entirely neglected for a time, and we are forced to the conclusion that the atmospheric conditions had a great deal to do with the path chosen by the spark. When the issue was narrowed by using only two rods at a time, rather more definite results were obtained, and the spark exhibited some preference for the round rod over the strip, but it was apparently the form rather than the metal which influenced the selection."

There is one other experiment made by Mr. Wimshurst, which I would briefly refer to. He constructed a model house, divided into three stories, and in the upper room there were metallic brackets representing gas and water fittings. Down the side of the house ran a lightning conductor, which could be put to earth in various ways ; the gas and water pipes were connected to the earth. Over the house stood a copper plate, representing a cloud. This plate was connected to the outer coating of one Leyden jar, while the other coating of the other jar (figure 8) represented the earth. In the first instance the lightning conductor was metallically connected with the earth, and successive discharges were passed into it from the cloud. There was then no sparking between the metallic roof and the gas and water fittings, either when the roof was connected to the conductor or not.

The importance of establishing a perfect connection between lightning conductors and the earth was shown by the following experiment :—

An artificial earth was constructed by Mr. Wimshurst, in a porcelain dish ; first, a layer of earth one inch in thickness was placed in the dish, then two sheets of metal, having each of them 28 inches of surface, were placed in the mold side by side, but separated by a space between the edges of 2½ inches. Over the whole another layer of damp mold one inch thick was laid, and the entire mass firmly consolidated by pressure. One plate was connected to the lightning conductor and the other to the outside of the Leyden jar, the discharge having to pass through the mold between the edges of the plates, which were 7½ inches long, and through the damp earth in which they were embedded.

Notwithstanding that the humidity of the mold was in excess of that of ordinary earth, in every case when a discharge occurred through the conductor from the cloud, part of the discharge leaped from the roof across a space of 1½ inches of air to the gas bracket, and got to earth that way; and this also occurred whether the lightning conductor was connected to the roof or not.

When the lightning conductor was not metallically connected with the roof then part of the discharge leapt through a space of air from the conductor to the roof, and thence from the roof through a second air space to the earth through the gas bracket.

The above experiment confirms my criticism of that part of Professor Lodge's lectures where he states the only effect of an imperfect connection between the conductor and the earth would be a tossing about of the ground and boring of holes in it; but, as I have pointed out, from the nature of the earth considered as a conductor, the check which an imperfect connection with it opposes to lightning would be very great. Mr. Wimshurst's experiment seems to me also to confirm the views expressed by me when referring to the failure of the elaborate lightning conductor system adopted for the protection of the Hôtel de Ville, of Brussels, which, regarded from the standpoint of "Modern Views of Electricity," Professor Lodge considered to be theoretically, and in all other respects, perfect. In that part of my article I stated I was disposed to believe the surging of currents through lightning conductors, to which Professor Lodge gives so much prominence, is more imaginary than real, but that I could readily imagine numerous conductors over a building may, under certain circumstances, be a source of real danger where there is an imperfect earth connection, for the electricity will then diffuse and dissipate itself wherever it can, and find its way to earth by numerous more or less imperfect channels;" and further on I state that such vagaries as breaking its way through chimney shafts to the heated soot inside, or through a wall to a gun, or fire irons, or a water tank, are, I believe, to be attributed primarily to the want of a good connection with the earth, and not to oscillations or surgings of the current in a conductor.

Professor Lodge describes an experiment made with two ribbons of tinfoil, 21 feet long and 3 inches wide. One of these was zigzagged backwards and forwards, with three sheets of paraffined

paper between the zigzags, and the other was wrapped as a spiral on a glass tube also insulated with three layers of paraffined paper.

It was found when the tinfoil zigzag formed the alternative route of the "experiment of the alternative path," the A space being 7 3, the critical or B spark was shortened from 11.1 to 0.6, and when the spiral was substituted for the zigzag, the B spark was lengthened to 6.4. It was further found that the insertion of a bundle of iron wires inside the glass tube had no perceptible effect whatever on the length of the B spark, which was 6.4 whether the bundle of iron wires was inside the tube or not at the time of discharge. This experiment, to my mind, is a very unsatisfactory one, and in lectures given professedly to assist practical men, in my opinion it would have been better to have omitted it.

Professor Lodge himself admits there are points in the experiment which "require further examination," but at the same time he bases argument upon it as if the experiment were a perfectly satisfactory one; this is a defect which seems to me to characterize the lectures of Professor Lodge as well as the articles on "Modern Views of Electricity." Able as they are, there is a tendency to fit the facts to the theory which is being championed.

The suggestion I should be disposed to throw out in explanation of the results obtained with the tinfoil spiral is that the insulation of the paraffined paper was not sufficient to effectually resist the passage of the high potential charge, and that probably neither in the zigzag nor spiral experiment did the whole of the discharge pass throughout the length of 21 feet. In the case of the spiral, the effect of the insertion of the bundle of iron was to further reduce the amount of discharge which followed the spiral course, the remainder and the greater part passing through the paraffined paper much in the same way as in the Wimshurst experiments, where the earth connector was not perfect.

If I follow the reasoning of Professor Lodge rightly, he seems to think it possible for a current of electricity to circulate round a mass of soft iron so rapidly as not only not to magnetize the iron, but also to meet with *no* resistance to its rate of motion.

He says, in reference to the experiments I am now commenting on: "Here is a magnetic time lag raised to an extreme. Professor Ayrton tells me they have noticed that the permeability of iron begins to diminish with very quick alternations. Here it is becoming virtually no bigger than that of air." Now, I am bold to say you cannot send a current round a mass of iron without doing something, and the work performed resists the rate of motion of a sudden electrical discharge. It is impossible to render inertia non-existent by rate of motion; on the contrary, it is just in those cases where there are rapid alternations of electric currents that the inertia opposed by a conductor or a mass of soft iron becomes the all-important element to be considered. I take it (but at the same time, I speak subject to correction), that if a perfectly hard bullet be propelled against a larger mass of equally hard matter suspended in space, the inertia effects exhibited by the mass will be as the square of the velocity of the impact, and I believe it will be found that magnetic inertia behaves in respect to electrical motion the same as material inertia does to mechanical motion.

If an electrical current be sent through the primary coil of an induction coil from a battery by an ordinary telegraph key or tapper, and a galvanometer be included in the circuit, it will be observed that the galvanometer needle hangs fire, and is not immediately deflected at the moment of contact, owing to the magnetic inertia opposed chiefly in this case by the iron core, and the chemical action or electrical motion in the battery is as a consequence retarded by this inertia. If the two ends of the secondary coil be joined together before depressing the tapper, it will be then observed that the galvanometer needle does not hang fire to so great an extent. When the tapper is depressed and the greater rapidity of deflection observed arises from the fact that an electrical current is developed in the secondary coil in the opposite direction to that circulating in the primary wire *instead of developing magnetism*, and if a series of momentary currents be now sent through the primary coil by means of the tapper, the greater part of the chemical energy developed in the battery will be converted into electricity *instead* of overcoming the magnetic inertia of the soft iron. Still, as the insulated wire of the secondary coil possesses magnetic inertia and opposes resistance, there will be a retardation of chemical action in the battery, but in a less degree as a consequence.

I have referred to this matter in an earlier portion of this article, where I have stated very positively that the whole of the mechanical force consumed in giving motion to an alternating dynamo machine, with the exception of a comparatively small percentage, is converted into electricity *instead of* magnetizing the soft iron cores of the revolving armature. Now it is simply impossible in Professor Lodge's experiment that the electrical discharge circulated round the glass tube, having a bundle of iron wires inside, without doing work of some kind, and such work, whatever it was, would retard the rate of motion, and therefore the conclusion I come to is, that as the insertion of the bundle of iron wires in the glass tube produced no observable effect, the electrical discharge did not circulate round the tube, but found an alternative path through the paraffined paper.

There is a practical experiment anyone can try for himself, showing the bearing of an imperfect connection between a lightning conductor and the earth, which Mr. Wimshurst's experiments has reminded me of. Take a Leyden jar, and one constructed of an ordinary test tube will be quite large enough for the purpose, surround the outer coating of the jar with a single layer of paper, grasp it in the hand, and charge it. After it has been charged, discharge the jar by means of a bent wire, taking care to press one end of the discharging wire firmly in contact with the layer of paper covering the outer coating before bringing the other end in the neighborhood of the conductor communicating with the inner coating. At the moment of discharge a very distinct shock will be experienced passing from the hand holding the discharging wire through the human body, and diffusing itself through the surface of the paper grasped by the hand and surrounding the outer coating. The paper owes what conducting properties it possesses to the small amount of moisture associated with it, and the polarization of this moisture at the moment of discharge opposes very considerable resistance. I think in this simple experiment we have practical evidence that an imperfect connection between a lightning conductor and the earth is sufficient to account in a common-sense manner for such vagaries as Professor Lodge refers to the oscillation and surging of lightning discharges in the conductor.

There is an experiment described in the second lecture of Professor Lodge, called the "Experiment of the Bye Path." It is shown at figure 10, and the following is the description given of it: "Take a yard of stout brass or copper rod an inch thick, arrange it in the path of a Leyden jar discharge, and then arrange as a sort of bye path or tapping circuit some very fine wire, such as Wollaston's platinum wire. It may seem absurd for any portion of the discharge to leave the massive rod and take the hair-like wire for preference, especially if an air-gap exists at A or B, or both. Nevertheless a portion *does* choose the fine wire path."

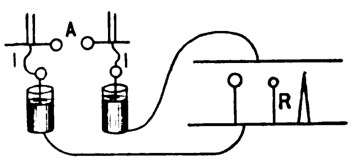

Fig.8.

Now, I think there is a simple explanation of the phenomenon observed without assuming that any portion of the discharge from the Leyden jar leaves the massive conductor. For discharge to occur, the magnetic inertia of the rod has to be overcome, and directly as the sectional area brought under the influence of the electric current, so will be the amount of magnetism developed in concentric rings at right angles to the rod. When a second conductor is arranged parallel to the thick rod, as shown at figure 10, a secondary current is developed in this wire at the commencement of the discharge, and another secondary current in the opposite direction to the first one is developed on the cessation of the discharge through the massive rod, and the magnetism developed in the thick rod *is less directly* as the amount of electricity set in motion in the wire Professor Lodge terms the "bye path."

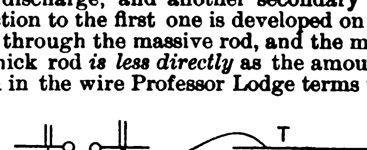

Fig.9.

The action is precisely the same as that observed by me on a much larger scale, when a lightning discharge struck the suspended wires of the Constantinople and Varna circuit, which I have described in an early portion of this article.

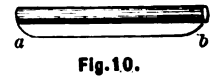

Fig.10.

There are two other experiments (figures 8 and 9) which I will briefly notice. Figure 8 is what Professor Lodge terms the "impulsive rush," and figure 9 the "steady strain."

Both of these experiments seem to me to be very practical ones. The impulsive rush represents what occurs when a discharge from a higher cloud strikes a lower one, which then suddenly discharges to the earth. Professor Lodge's experiments shows that a discharge under such conditions chooses the best conductor, even if it be not the nearest object to be struck, and the fact that the conductor is pointed or not seems to make no difference.

In the experiment of the steady strain where the difference of potential between the clouds and the earth is brought about in a gradual manner, rising from zero until the difference of potential is sufficient to break down the dielectric, then it is found that a pointed conductor though farther from the cloud than other non-pointed conductors, is much more effective in bringing about discharge; indeed, under such conditions, complete discharge may be brought about without any lightning flash occurring.

I take it that in the ordinary course of nature differences of potential between the clouds and the earth are more often reduced quietly than by disruptive discharges, and that when thunderstorms do occur "impulsive rushes" are the exception.

I, myself, believe in a limited protective area, and I think a single point, as long as it remains a point, is as effective, if not more effective, than a number of points.

In an earlier portion of this article I have incidentally given my reasons for such belief, where I have suggested an explanation of how it is a point will discharge a Leyden jar through a considerable space of air.

A great many years since, in conjunction with my late brother, I tried the effect of removing the collecting comb from a frictional machine, and substituting a single point in its place.

The experiment was tried in a room heated to a high temperature, and the dryness of the atmosphere was indicated by a hygrometer. The machine seemed to work as perfectly with the single point as the comb, the same number of turns charging a battery consisting of six half-gallon jars in both cases.

There are a few other experiments described in the lectures I am commenting upon which I should like to have made a few remarks upon, but I feel the time has come when I must bring this article to a conclusion.

The main points on which I am at issue with Professor Lodge are:—

1. I believe an electric current commences to flow through the centre of a conductor, and not first down the outside, as Professor Lodge considers to have been abundantly demonstrated:—

2. I do not believe lightning discharges oscillate and surge about in conductors; and, further, I consider abundant evidence has been adduced to show that an imperfect connection between a lightning conductor and the earth is quite sufficient to explain those apparent vagaries where the lightning has left the main conductor and reached the earth by other channels.

I quite agree with Professor Lodge that it is not a question of "flights of fancy," but one of downright fact. The question whether the flow commences in the interior or the outside of a conductor can be readily determined, I believe, by direct experiment, and I hope to be permitted shortly to do this. I have called attention to the fact that we have Leyden arrangements involving time in their discharge, as well as Leyden arrangements whose rate of discharge is so great as not at present to be measureable. We can follow the discharge and observe what occurs when this is taking place in the slower Leyden arrangements, and what we there observe I contend helps us to understand what occurs when an electrical discharge takes place much more quickly.

If a lightning discharge be a rapid oscillation of electricity on the outside of the conductor, there must be something to produce such oscillations which are not observed in the discharge of slower Leyden arrangements. I think, therefore, it would not be too much to ask Professor Lodge, on public grounds, to explain how he accounts for the surging about and oscillations of lightning discharges, on which so much stress has been laid in his two lectures on the protection of buildings from lightning.

POINTERS.

.... ELECTRICITY can now be produced by steam at 8d per kilo watt per hour.—*W. H. Preece.*

.... THE holiday tourist when admiring the splashing water dashing over the stones hardly realizes that the money loss is as if the foam were composed of flakes of silver.—*Professor Ayrton.*

... IT seems incredible that having utilized this great power of nature to such a wide and general extent, we should be still in a state of mental fog as to the answer to be given to the simple question—What is electricity?—*W. H. Preece.*

... THERE is no branch of physics pursued with more zeal and with more happy results than that of electricity with its allies, and there is no branch of science towards which the public looks with greater hope of practical benefits.—*Sir Frederick Bramwell.*

.... WE are learning daily what sort of properties the ether must have. It must be the means of propagation of light; it must be the means by which electric and magnetic forces exist; it should explain chemical actions, and, if possible, gravity.—*G. F. Fitzgerald.*

.... I THINK, therefore, that it is not in the inventors that we have to look for goaheadedness, but to men of capital who are technically instructed. I think it is technical instruction among the moneyed classes that has developed electrical engineering so much in America of late years.—*Professor George Forbes.*

ABSTRACTS AND EXTRACTS.

DISCUSSION ON LIGHTNING CONDUCTORS AT THE BRITISH ASSOCIATION.[1]

ON the 11th September, Sections A and G joined for the purpose of debating on the question of the "Construction and Efficiency of Lightning Conductors," the leaders of the discussion being Mr. W. H. Preece, F. R. S., and Professor Oliver Lodge, D. Sc., F. R. S. Professor Fitzgerald was in the chair, and called upon Mr. Preece to open the debate.

Mr. Preece, in commencing, commented upon the very small amount that had been learned about atmospheric electricity during the last century. Until quite recently Benjamin Franklin's work, published 140 years ago, contained almost all that we knew on the subject. As late as 1881, there had not been published even a code of instructions with relation to the methods to be adopted to protect buildings from the destructive effects of lightning discharges. Hence in 1878, it was agreed to establish a conference to consider the matter in its practical aspects, and to draw up such a code of rules as was needed, and for this purpose the assistance of the members of the Institute of British Architects, the manufacturers, and press of this country was requested. At the 1881 meeting of the British Association a report was presented by this conference. The results arrived at were to be found *in extenso* in a book on the subject published by Spon. The following passage, extracted from this report, would form the basis of a good deal of the debate: "A lightning conductor fulfills two functions—it facilitates the discharge of the electricity to the earth, so as to carry it off harmlessly, and it tends to prevent disruptive discharge by silently neutralizing the conditions which determine such discharge in the neighborhood of the conductor. To effect the first object a lightning conductor should offer a line of discharge more nearly perfect and more accessible than any other offered by the materials or contents of the edifice we wish to protect. To effect the second object the conductor should be surmounted by a point or points. Fine points and flames have the property of slowly and silently dissipating the electrical charges; they, in fact, act as safety valves. If all these conditions be fulfilled, if the points be high enough to be the most salient features of the building, be of ample dimensions, and in thoroughly perfect electrical connection with the earth, the edifice with all that it contains will be safe, no matter from what direction the storm cloud may come, and the conductor might even be surrounded by gunpowder in the heaviest storm without risk or danger. All accidents may be said to be due to a neglect of these simple elementary principles. The most frequent sources of failure are conductors deficient either in number, height, or conductivity, bad joints, or bad earth connections." The paragraph concluded with the emphatic assertion—which assertion the speaker was there to defend—that "there is no authentic case on record where a properly constructed conductor failed to do its duty." The conference had not failed to take notice of the teaching of modern theory. It had, as its report explained, assumed "the conductivity of equal lengths and weights of iron in the case of steady currents of electricity," and, moreover, that "the suddenness of lightning discharge modifies the conductivity." The report was signed by Grylls Adams, W. E. Ayrton, Latimer Clarke, E. E. Dymond, G. Carey Foster, D. E. Hughes, Hayter Lewis, W. H. Preece, G. J. Symons, and J. Whichcordy, all of whom had had great personal experience of lightning conductors. Lectures had been instituted by the Society of Arts in memory of the late Dr. Mann, who had done a good deal of experimental work with regard to lightning conductors in South Africa; and since this was the case, the subject of protection of buildings from injury by lightning had been chosen as the subject, and Professor Oliver Lodge had been chosen as the lecturer. Expected to eulogize the work of the British Association Conference, he had, like Balaam of old, disappointed those expectations by condemning the conclusions to which that conference had come. If all that Dr. Lodge had asserted was true, the whole work of 140 years had been wasted—no lightning conductors could possibly protect, nor was it possible to safely lead away a lightning discharge to earth.

Mr. Preece said that his duty now was to show that there had been a good deal that was fallacious both in Dr. Lodge's lectures to the Society of Arts, and in a paper of his upon the same subject which had appeared in the *Philosophical Magazine* (August, 1888). In the first place, according to Dr. Lodge, a lightning conductor formed part of the path of the flash. This was never really the case. The lightning rod was erected to prevent the flash occurring; and the fact of its being struck was sufficient to prove it a faulty protector. But even allowing that the lightning does actually discharge through the rod, the latter would form a very small fraction of its whole path. Much depended on the height of thunder clouds. Dr. Mann, in South Africa, had estimated their height as about 650 feet; M. Lacoine, in Turkey, had made measurements which gave a height of 325 feet. These results were probably accurate ones. Mr. Preece had himself come to the

1. From *Industries*, November 9, 1888.

conclusion, from recent observations in Wales, that our lightning flashes had an average length not greater than 500 feet. Experiments carried out by Sir William Thomson and Dr. Warren de la Rue, with regard to the striking distance across an air space for steady currents, showed it to be, speaking from memory, about 30,000 volts per centimeter. If a flash, then, were 500 feet long, and it varied directly as the striking distance, then the measurements given in Dr. Lodge's papers would be about right; but in all probability the striking distance did not vary directly as the length, particularly in the case of alternating currents. According to Mr. Acheson's investigations on the currents produced by transformers, the striking distance varied as the cube of the electromotive force into the capacity. Hence, if this were correct, the electromotive force necessary to force an electric current through the air was considerably less than was formerly supposed.

Moreover, a flash of lightning always goes along a path that has been prepared for it. It does not come down with a rush upon objects which it strikes. Wherever lightning flows, all evidence shows that preparation has been made for its passage. Again, an assumption of the instantaneity of the flash had been made—an assumption which he (Mr. Preece) was not prepared to grant. There was no proof of it. How long the flash really lasted it was impossible to say. There were dark flashes, which never are visible at all—cases were on record where these have been fatal. The effects of lightning discharges upon telegraph lines were good arguments against its instantaneity. When the lightning does enter a wire, currents are produced of sensible duration. The compass needles on board ship could not be affected, as they are, by lightning, if the flashes were not far from instantaneous. On this point photography should be helpful. Then came the question of the alleged oscillatory character of the lightning flash—an idea due rather to mathematical reasoning than to absolute observation. He was sorry to say that there were some mathematicians who allowed themselves to become the slaves of their science. He might say that engineers had no very great respect for mere mathematical development unless it were supported by experiment. And this theory of the oscillatory nature of a flash of lightning was one of the mathematical deductions that must be received with caution. Several facts were opposed to the theory; electro-magnets certainly were excited for a sensible length of time by a lightning flash; needles were magnetized and demagnetized; electrolytic actions were effected. He had frequently heard letters telegraphed by lightning. On one occasion he distinctly heard the letter "R" signaled by this means—this letter involving three distinct currents to produce it. Even "G," requiring eight alternations, had on one occasion been produced. Either, therefore, the flash could not oscillate at all, or else the oscillations must be exceedingly slow to produce these effects. It was very doubtful whether this oscillatory movement took place in lightning flashes at all. It might occur in condensers; but they were not dealing with condenser discharges. Flashes of lightning were more nearly analogous to the breaking down of the dielectric than to the external discharge of the condenser where oscillations do occur. Of the existence of *slow* oscillation in the flash there was abundant evidence. Professor Elihu Thomson had proved it to exist in some cases by wagging his head while observing a flash.

To go on to a point which Dr. Lodge had raised, and which was of immense importance. As a parenthesis, there was no man who had worked so thoroughly and honestly in this direction as Dr. Lodge, and no one with whom it was a greater pleasure to carry out a discussion, because of the harmony and good feeling that he showed. Dr. Lodge had performed the following experiment: He had taken a Holtz machine, H, which charged one side

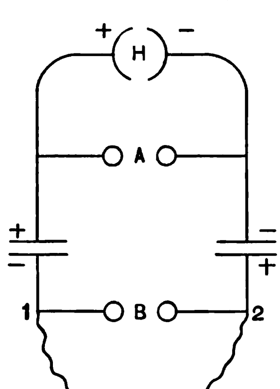

FIG. 1.

of the condenser with positive, and the opposite side with negative, electricity. Then if the points 1 and 2 of a discharger (as shown at the time on a blackboard) be connected by an "alternative path," L, of iron or copper wire, the distance between the knobs B, across which the spark will pass, is much greater than if L is absent. The real discharge is determined by the knobs A. When the condensers discharge, there is simultaneously a discharge at A and B. Dr. Lodge explained this by supposing that, on account of the oscillatory nature of the discharge, there was self-induction in L, a kind of obstruction which caused the charge to pass across at B, rather than travel through the conductor. The spark was longer with copper than with iron as an alternative path. He (Mr. Preece) would, however, give as his explanation of the phenomenon, that the increased spark in the case of copper is owing to increased charge in the condenser; iron throttles the charging current. Dr. Lodge argued from the discharge alone. But it was possible to argue from the charge also. A Holtz machine would set up little pulsations of electricity. Dr. Lodge said that because the spark is longer with copper, copper has more self-induction than has iron. He (Mr. Preece) would say that, as the charge is a pulsating one, the extra spark length is due to the self-induction in iron being greater than in copper.

There were many objections to this self-induction theory, yet it looked as if Dr. Lodge were on the brink of a discovery in static electricity. But that gentleman had apparently overlooked a paper by Professor Poynting, which, had he studied, he would have found proofs that energy passes through the dielectric and not through the conductor, and he might have applied this principle to his experiments. He (the speaker) himself was not sure that Dr. Lodge would not find that there was something in the contact between the conductor and the dielectric. When a charge was passed through a chain of persons, those who suffered most were the end ones. There was some effect between the surface of terminals and the air, of which we are at present ignorant. He wished also to note the fallacy of Dr. Lodge's statement that a lightning conductor protects no area whatsoever. What, then, was the use of it? There was sufficient evidence in the report of the conference to show that this was not the case. Moreover, Dr. Lodge had asserted that extended points were useless; the conference had pronounced them essential. The conference was supported by the experience of the past; Dr. Lodge by mathematical assumptions. Finally, he would say that he had done his best to uphold the conclusions come to by the lightning rod conference. He had feebly endeavored to prove Dr. Lodge's views in some respects fallacious; and he felt that, whichever side were the more successful in the discussion, at least it would have the advantage of bringing to their minds the true theory of electricity, shadowed forth by Professor Fitzgerald in his inaugural address, an address which he believed would mark this meeting at Bath as an epoch in the history of electricity.

Professor Oliver Lodge, D. Sc., F. R. S., in commencing his defense, confessed that he could not boast of a practical knowledge of lightning conductors anything like that which Mr. Preece had obtained from the half million conductors under his supervision, not having himself a single rod under his control. The house in which he lived had not one, nor had the college at Liverpool with which he was at present associated. He had several times asked for one to be put up there, but had been told that it was cheaper to insure. There must be some fallacy in the argument that, because an insurance company is willing to pay if a thing is damaged, it is therefore nobody's business to protect it from damage. However, manufacturers often acted on this principle. It was perfectly true that, if his views were correct, very few buildings were effectively protected at the present time; but then it was also true that, if they were correct, lightning conductors would in the future cost not many more shillings than they at present cost pounds—which, if they are equally effective, would be no slight advantage. Mr. Preece had been poking fun at mathematicians. He (the speaker) was quite prepared to argue the question in hand without the use of a single symbol. Mr. Preece began by saying that there was not an authentic case, no record of a properly constructed conductor failing to do its duty; but a large number of such failures were to be found described in the report of the lightning rod committee. There was one noteworthy one. A brass rod one inch thick fixed on a steeple in Italy had been smashed to pieces and the steeple destroyed, and this had been witnessed by a large number of people. In his lectures last spring, he had quoted as the best protected building in the world the Hôtel de Ville at Brussels, upon which M. Melsens had spent so much time and trouble. That building was protected by innumerable conductors, with admirable earths, and bristling all over with points at the top. Last June it was set on fire by lightning. Books had been written about the elaborate method in which it had been protected, but few particulars of its destruction had been published. Next, Mr. Preece had had a hit at him, where he admitted that Mr. Preece had had the advantage. That gentleman had quoted a sort of Midlothian speech of his, in which he had made an erroneous statement; but he was not introducing that as a statement of mathematical calculation, or anything else of the sort; it was a mere parenthesis thrown in very hastily. Of course, one ought not to do those things; but yet when one wrote much one was very apt to make hasty statements. When asked by the Society of Arts to lecture on lightning conductors, he had resolved to say something about self-induction, having observed that the lightning rod conference had not referred to that question under the

name of magnetic inertia or any other. He happened to be writing a paper which appeared, he thought, in *Nature*; and in that paper, having regard to the magnetic permeability of the two metals, copper and iron, he had stated that, in regard to the magnetizability of its substance, iron was 90,000 times worse than copper. He meant to say, therefore, that although iron was cheaper, was more difficult to melt, had a higher specific heat, and in a variety of ways was better than copper, yet in regard to this electro-magnetic inertia it was enormously worse. Before actually giving the Mann lectures, however, he made a few experiments on this point, and to his surprise he found that, so far from being worse, iron was often rather better; and that even a thin wire of iron carried off the discharge better than a thick wire of copper. This experiment naturally and at once effected his conversion. The experiment referred to was that of the alternative conductor; it might be of iron or copper or any other metal, of any thickness they wished to experiment upon. The top part of the arrangement sketched by Mr. Preece was of no particular interest; at least they need not attend to it now—the bottom part was the thing. The B spark measured the electromotive force which drove the current through the alternative path. They should adjust the B part until the flash produced there did not know which way to go—whether to go through the wire or through the air. Half the sparks failed when that is attained. With a spark micrometer at B they measured the distance, and thus obtained the electromotive force which is on the verge of succeeding in driving the contents of the jar through the wire. He tried first a thick copper wire, and after a thin iron wire of the same length. He found that a greater distance of spark, a greater electromotive force was needed to drive the contents of the jar through the thick copper wire than through the thin iron wire. Whatever explanation might be given of an experiment of that kind, a direct intimation from heaven could be no clearer. For some reason or other the copper and iron are at least equally good. He did not press the point that iron is *better* than copper, and had never stated that copper had more *self-induction* than iron—that would be a mad thing to say; but it might happen for some reason or other, that copper obstructed the current more than iron. He preferred, however, to say that the two metals were equal. Mr. Preece said that the function of a lightning conductor was to prevent a flash from striking the conductor—that is to say, that a lightning conductor ought never to be struck, or it failed; but they are struck, because they get melted, and yet in an earlier sentence Mr. Preece said they never failed. He did not know which of those statements was to be taken as correct. If a lightning conductor could prevent a flash from occurring by its point action, well and good; but he had shown in the lectures (he would not trouble them by repeating a statement of the experiments) that there were cases where a point had no protective action whatever, when it can be struck by a thick and heavy flash. There were other cases where the point acted with a brush or fizz, and neutralized the electric charge without a flash. But they could not always depend upon it doing that, and so the lightning rod had two functions—one preventive if it can, and the other to carry off a flash when it cannot help receiving it. But they must remember that a flash—at least the electric charge—has always a certain amount of energy, and that it has to be dissipated somehow. It is not a question of a certain quantity of electricity which has to be conducted to earth and then there is an end of it; there must be a certain amount of energy, and they must dissipate it somehow. They could not expect to *hocus pocus* energy out of existence by saying they would conduct the charge down to earth; the quicker they tried to conduct it down to earth the more surging and violent disturbances they were likely to get. It might be better to let it trickle down slowly by using a moderately bad conductor than to rush it with extreme vehemence down a good conductor, just as it would be safer to let a heavy weight suspended in a dangerous position slide down rather than to let it drop as quickly as possible. Concerning the length of flashes, he wished he had first-hand information, but he had none; it was one of those things which meteorologists must determine. It was very important to know the length of the flash. He had seen it stated in books that the flashes were a mile long and perhaps more. Mr. Preece thought they were only 500 feet long; that was a matter of fact which could be investigated; but that was a matter upon which he had no direct first-hand information. As to whether the spark length is proportional to the distance or not, he would say that the experiments with oscillating currents, to which Mr. Preece magnanimously called his attention yesterday, were conducted with alternating dynamos between points. Now the area of cloud and the area of earth below it are not points; they are flat surfaces, like the coats of a Leyden jar.

Mr. Preece remarked that they were alternating transformers, when Professor Lodge replied that they were alternating currents as used in practical commercial work discharging between points. There the law did not seem to hold; but then it ought not to hold, so that would be all right. But between flat surfaces it ought, and the spark length ought to vary with the difference of potential between the two flat surfaces. At the same time, if there were points on the earth's surface which were big enough, and if these points determined the flash, then the law of proportionality would not hold. However, the laws concerning discharge in dielectrics were well known, and were scarcely matters for argument. The circumstances of an oscillating current did not apply as regards the length of the spark, because until the discharge occurred there was no oscillation; it was a mere static charge. The earth and the cloud above it are exactly like the coats of a Leyden jar, which are preparing to spark into one another, and which do spark into one another when the difference of potential rises to a certain maximum, and the air between is broken down. The duration of flashes was another point on which much valuable work might be done by meteorologists and photographers. He had seen lightning flashes which certainly appeared to last two or three seconds. He could not imagine that it was one flash which was doing that; he thought it was a series of multiple flashes succeeding one another very rapidly. If any kind of flash can be shown to last long, it is an argument that that kind is not oscillatory. The fact that they deflect a compass needle did not prove anything about it; it did not prove anything concerning their duration either, because a ballistic galvanometer is deflected by momentary kick. A momentary blow given to a thing can deflect it, the blow having ceased long before the motion has ceased which it produced.

The difficulty of the magnetizing power of lightning was one of the strongest points Mr. Preece had adduced. A flash magnetized steel bars, deranged the magnetism of a ship's compass, and produced other magnetic effects. An oscillating current should not produce such effects. An oscillating current with decaying amplitude is used by Professor Ewing to demagnetize steel, not to magnetize it. The oscillating current would have a gradually decaying vibration. That would demagnetize things, but it ought not to magnetize. It does magnetize them; therefore how can it be a current of this kind? But then the same difficulty would be felt with the Leyden jar discharge. The Leyden jar discharge is certainly oscillatory, because it has been seen to be so, when the sparks have been analyzed in a revolving mirror. And yet it magnetized steel needles when sent round them. He did not fully understand that point, and he hoped Lord Rayleigh would say something about it. Mr. Preece was quite right in saying that the whole theory depended upon the existence of oscillations. As far as the theory was concerned, he (Professor Lodge) had merely called attention to these oscillations —which were well known in the case of Leyden jar discharges, and of which the mathematics had been worked out—and pointed out that they applied also to lightning, which he did not think had been much noticed. A pendulum is an analogue of them. Raising the pendulum represents the charging of a jar; charge it more and more, and then discharge it—that is, let it go. When you let a thing go, it naturally swings before coming to rest; it need not, it may meet with too much friction. Suppose it were oscillating in treacle, it would then have a dead beat motion down. It may be a slow leak, the discharging of a condenser through a leak, in which case it would come down very slowly. Those are cases in which there is no oscillation, and it entirely depends upon the friction—the viscosity it meets with. If the friction is very great, if it is like a leak, then it would go down slowly, and there would be no oscillation. If the friction is small, and if there is inertia, then it must oscillate. Mr. Preece admits the inertia. Suppose a Leyden jar going to spark, it possesses potential energy, like a raised pendulum or bent spring; the instant it sparks a current rushes round. They had then a circular current, which was well known to deflect compass needles, to produce magnetic effects. That is the electro-kinetic inertia represented by the ordinary inertia of the spring or pendulum when it passes the middle position. You have first a static charge; then, while it is flying past, you have a current, and magnetic effects, and kinetic inertia, which carries it on to its other extreme position of static charge; and so you have these oscillations gradually dying out on account of the friction. If they made it oscillate in water instead of in air, the oscillations would die out more quickly. They would die out for two reasons; partly because of friction, which generates heat; partly because waves are produced. If they made it oscillate in water, the surface would be disturbed, and waves would travel along; part of the energy would go in heat, and part in waves—that is, producing radiation, or light, as they might call it if it were only quick enough to affect the retina.

He did not know what was the energy of a lightning flash, and wished there were some means of determining it. As to whether lightning was likely to be oscillatory or not, that was a question of resistance (or friction) compared with the capacity and inertia of the discharge. The smaller the capacity, the more likely it was to be oscillatory; the bigger the inertia, the more likely it was to be oscillatory. The capacity discharged in a flash is small, for the quantity is not great, while the potential must be enormous. Finally, there was the question of the area of protection. Mr. Preece's theory on this point could be obtained from a paper in the *Philosophical Magazine*, and the area protected according to this theory was so small that they might almost give it him without argument. Suppose A B a conductor and D E the ground line. Taking the corner of a square (two of whose sides

are A B and D E) remote from B, describe the curve A E, and similarly D A on the other side. Then A D B E would be the protected region—which was not much. If they applied that to every point on a house, they would want a conductor on every point; but Mr. Preece meant that you must put up a rod of gigantic height to bring the whole house into the area. Even then they would not be safe. Why did he object to such a bit of protection as that? Mostly because he thought that areas of protection directed one's attention to side issues—to a thing which it is better not to

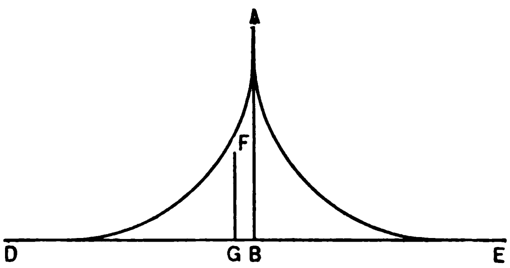

FIG. 2.

think about, because there is no certain area of protection. Take another rod (F G), completely enclosed in this area of protection, and lead it up from the ground to near the lightning conductor, so as to leave a little spark space. If "area of protection" has any meaning, that rod ought to be protected; but he said that when a lightning flash (that was merely an assertion, and they need not believe it) struck that conductor A B, they would almost certainly get a spark down to this supplementary rod F G, which would take its share and assist in conveying the current; therefore, it is not protected. If a man held a lightning conductor when the flash passed down it he would most likely be killed, and if it passed through gunpowder—well, he did not know about gunpowder, because gunpowder got blown about. It did not matter about the earth; let the intended conductor have a good earth and this supplementary one a bad earth, still the same effect will occur; a spark is likely to occur if the distance be not too great. He said that this is so because he had made experiments in the laboratory after this fashion, amongst others. He took a rod which might be of copper as thick as they pleased, he put it in circuit with a Leyden jar, sending the discharge through the rod. This was a solid rod of copper; take a Wollaston platinum wire, or any other wire as fine as possible so as to make the contrast greater, and arrange it to make a kind of tapping circuit; arrange so that the bottom end shall be in contact with the rod, and the top end an eighth or a sixteenth of an inch away. There they had a splendid conductor, better than any lightning conductor ever was. They would have no trouble about earth, as they had a little tapping circuit close to it—the Wollaston wire, which they could hardly see. It seemed absurd for any portion of the discharge to leave this inch-thick conductor to jump across a sixteenth of an inch of air space, and to make for the little thread of wire. Nevertheless a portion of it does, and from every spark that goes through the conductor a side branch goes to that little wire. There was one point where Mr. Preece had not made out the full strength of his case. A thunder cloud is not a good conductor—it is like a spangled jar, consisting of drops of water with spaces between them. There was, therefore, no guarantee that the whole discharges at once. There might be a kind of dribbling away, and thus the oscillatory sudden rush might not take place.

There was another recently discovered point, which could only just be touched on—viz., the effect that the light of one spark had in helping in the formation of others. A spark from one induction coil was able to start a spark in a second coil merely by its light. That was why he said that the idea of the protection of areas was misleading. If one flash caused a lot of others, it was not safe to have that one.

Mr. Glazebrook had just asked him to describe the effect of light in producing a spark. There was no difficulty. Take a common induction coil; separate its terminals till the spark will just not pass. Expose them to the light from a burning magnesium ribbon, and sparks would at once pass, and would stop when the light is removed. The light from the spark of another induction coil or a Holtz machine would have a similar effect. The light of a spark, or ultra-violet light in general, seemed to diminish the transition resistance between the metal pole and the air, especially in the case of the cathode.

The Hon. Ralph Abercromby exhibited a number of photographs of lightning flashes selected from those collected by the Royal Meteorological Society. The first question which might be answered by these photographs, he thought, was—Is there any evidence of the duplication of flashes; that is, of one flash rapidly succeeding another? Of this the photographs seemed to give no evidence. One of them, showing one bright flash with three apparent repetitions of that flash in different places and of varying intensity, seemed to point to an affirmative answer to the question; but they had good reasons to believe that these repetitions were due to reflections of the light from the back of the glass of the photographic negative. Flashes were frequently seen coming close after one another, but there was no photographic evidence that they followed the same path. One photograph from Massachusetts showed the whole field of view filled with fine threads of lightning. He thought that it was important to make investigations in order to find out what influence rain or hail had upon the form of the flash. Photography gave conclusive proofs of the non-instantaneity of flashes of lightning, which seemed to go meandering about the air in an aimless sort of way. There was one evidence bearing on this question which had been adduced as evidence, but which the photographs before the committee did not confirm. In fully half of the photographs the lightning does not cover the plate as a streak, but has more or less of a banded nature, something like a ribbon. It had been suggested that this apparent breadth might have been due to the shaking of the camera, but they had evidence that this was not the case. One of the most remarkable photographs showed three white flashes and a black one. This black flash, according to an early idea of his, was due to the inversion of the photograph, which sometimes, as all photographers knew, took place owing to over-exposure. M. Janssen had made to him a very valuable suggestion, that this might be the evidence not of a peculiarly bright flash which over-exposed the plate, but of a slow moving flash which gave time for the plate to be exposed. Of course it was impossible to say much from one case, but he thought that this was a remarkably brilliant idea. With reference to Mr. Preece's remarks on the height of lightning clouds, it was possible to have them only 500 feet high; but this was very low—in the majority of cases they were certainly very much higher. Electrical disturbance is confined certainly to the lower 10,000 feet of the atmosphere. In connection with the practical bearing of that, he might mention that in Norway they had two kinds of thunder storms. In the summer he believed the thunder clouds were high, and very little damage was done; on the contrary, in the winter time the thunder storm clouds were very low, and the churches frequently get struck. On practical applications he could not offer an opinion; but he was quite certain that great good would result from that discussion.

Lord Rayleigh said that he had no special experience of lightning rods, and could only speak from a general knowledge of electricity. In such cases as the one in point, anything that stood on an *à priori* foundation merely should be received with diffidence; yet it seemed to him that Professor Lodge's experiments appeared likely to have an important bearing on the subject of lightning conductors. He could not see how experiments dealing with the thing of all others most like lightning that they could produce in the laboratory could fail to have such an application. Professor Lodge asked one question, and he thought mentioned his (Lord Rayleigh's) name in connection with it, as to how it could happen that an oscillatory electric current—that was, say an alternate electric current beginning at a finite magnitude and gradually dying away—could produce magnetizing effects such as they well knew it did in some cases; and he instanced the very opposite behavior of slowly dying away alternating currents in the experiments of Professor Ewing and of others, in which such an arrangement was precisely the one adopted in order to get rid of even the last traces of magnetism. The question was a difficult one certainly, and he had intended, in fact, to make some experiments upon it himself; but he was inclined to think that the explanation might, perhaps, be sought in a circumstance very much akin to the one with which they were now dealing, viz., that the steel needle, which was to be magnetized, say, by the discharge of a Leyden jar flowing through a spiral enveloping the needle, was itself a conductor of finite dimensions, in which circumferential currents would be induced. These circumferential currents would, at first, at any rate, protect the interior of the iron from the direct magnetizing action of the enveloping helix. They must think not only of the action of the oscillating current in the helix upon the various parts of the needle, but also of the action of the currents developed in the steel needle itself. It ought to be well known, at any rate it had been well ascertained, that at different depths in such a steel needle they would find very often different degrees and even different directions of magnetization. It seemed to him possible that, if this was thoroughly followed out, they would be better able to understand what was certainly a fact—that a current whose whole value, in some cases measured algebraically, is zero, and is certainly alternating and gradually dying away, does, nevertheless, produce and leave behind it the effect of strong magnetization. It seemed to him that it was only by actual experience of lightning conductors that the question could ever be finally settled. Laboratory experiments must be most important as suggestions, but he thought that no one would wish finally to adopt any system or change any system of lightning protection without actual experience on a large scale.

(*To be continued.*)

.... APPLICATIONS of science and discoveries in pure science, act and react the one upon the other.—*Sir Frederick Bramwell.*

THE DEPTFORD ELECTRIC LIGHTING STATION.[1]

THE total number of gas jets fixed throughout the area which is usually understood when we talk of London, may be roughly estimated at 5,000,000. If all these jets were to be replaced by electric glow lamps, giving the same amount of light, the power required to generate electric current for these lamps would be about a quarter of a million horse-power. The London Electrical Supply Corporation, Limited, propose to supply eventually over a quarter of a million lights, or about one-twentieth of the total supply which would be required for the whole of London. But even this twentieth is a very large amount, as could be realized by the party of press representatives who were invited to view the Deptford works on Wednesday last. The site of the works comprises about 4 acres, with river frontage. The coal will be unloaded from the steamers by hydraulic skips, and run on two railways, one on the ground, and one overhead, into the boiler house. The buildings now in construction consist of one boiler house and two engine houses, the whole occupying a space of 210 feet by 95 feet.

In preparing the plans of the station, Mr. Ferranti, the engineer to the company, has provided for future extensions by leaving room on either side of the building, so that more boilers can be installed by an extension of the building towards the river, and more engines and dynamos by an extension in the opposite direction. The boiler house is 195 feet long by 70 feet broad, and nearly 100 feet high. In it are now being erected 24 Babcock and Wilcox boilers, part of them on the ground floor and part on the first floor. Above this there is another floor, on which about 4000 tons of coal will be stored. The coal will be brought down to the boiler floors by chutes. At each end of the boiler house is a group of chimney stacks, four in each group. Each stack is 6 feet by 18 feet by 130 feet high. Green's economizers are also provided, and the boilers will be worked with forced draught on the closed ash pan principle. The engines and dynamos will be placed in the two contiguous rooms, each 195 feet long and 66 feet wide by about 85 feet high. The engine house will be provided with an overhead traveling crane capable of lifting 25 tons.

In the first engine room there will be erected two Ferranti dynamos, each of a capacity of 25,000 lights, or about 1500 electrical horse-power. Each machine will be driven by an independent vertical compound condensing steam engine, the transmission being by 40 cotton ropes. The armatures of these machines are 12 feet six inches diameter, and one inch thick; the speed is 168 revolutions, and the working pressure 10,000 volts. One terminal and the corresponding conductor of the concentric main will be grounded. With so high a pressure as 10,000 volts, it is of course absolutely necessary to make it impossible that any of the attendants could touch a portion of the other circuit. All dangerous parts will therefore be boxed in, and to prevent the possibility of anyone opening the covers of these parts whilst the machines are at work, Mr. Ferranti has adopted an exceedingly ingenious device of locking these covers magnetically by means of the exciting current, the cover itself breaking the exciting current when open. These two machines will suffice for the supply of the lights which have already been taken up by the customers of the company in the city and other parts of London; but eventually these machines will only be used for the day service, the heavy lighting being done by two machines of much larger dimensions, which will be erected later on. These large dynamos will each have a capacity of about 10,000 h. p., and will be direct driven by vertical compound engines of 5,000 h. p., one engine being placed on each side of the dynamo. At first only one engine will be erected to each dynamo, so that the capacity of the station will be about 100,000 10-c. p. lamps, supplied from one machine, the other machine being in reserve. If the demand for current has sufficiently increased, the other engine will be added, and the capacity of each dynamo will thus be brought up to 200,000 lights. Further extension of the plant will be in machines of this type.

The engines are being constructed by Messrs Hick, Hargreaves & Co., Bolton, and the framing of the dynamos by Messrs. Maudslay, Sons & Field, London; Mr. Ferranti manufacturing the electrical parts of the dynamos at his works in Charterhouse Square. A traveling crane of 50 tons lifting power will be provided for the erection of the large steam dynamos. There will be separate condensing engines provided to condense the steam from all the engines. These will be erected in the first engine room, where also the pumps for the hydraulic gear and the exciting dynamos will be placed.

The large dynamos will have 39 ft. armatures, and be direct coupled to the engines, the working speed being sixty revolutions per minute. The current will have a period of 8000 alternations per minute. One of the most interesting parts of the whole undertaking is that which may be broadly described as the distributing plant. The current will be conveyed from the station into local centres in London by concentric mains, consisting of an inner copper tube $\frac{3}{16}$ in. thick, a layer of insulation, and an outer tube $\frac{3}{16}$ in. thick, the diameter of the main being $2\frac{3}{16}$ in. This main is made in lengths of 20 ft., which will be joined by special couplings, suitable provision being made for expansion and contraction. The main will be simply laid into the ground without any other protection than is afforded by the surrounding earth, and the outer conductor will thus be grounded over its whole length, rendering the handling of this main perfectly safe. Where possible the mains will be laid along the railways, but duplicate mains will later on be laid also along the streets. At the local centres there will be transformers bringing down the pressure from 10,000 to 2,400 volts, the standard now adopted at the Grosvenor Gallery station, and the distribution of the 2,400 volt currents will also be effected by concentric mains. Finally these currents will be brought down to 100 volts by other transformers, and only the low tension current will be supplied to the customers. The supply will be by Ferranti meters, which have now been perfected to such a degree that a 200-light meter will begin to register with one lamp. Some very delicate trains of wheels are required for these meters, and as the company had some difficulty in obtaining these trains from the clockmakers in this country, they have sent a member of their staff to America with instructions to buy a complete set of machinery of the type used in the manufacture of Waltham watches, and bring it over. With this machinery the company will be able to turn out some 15,000 meters annually. The Deptford electric light station is certainly the most gigantic work of this class which has yet been undertaken anywhere, the American central stations not excepted; and the greatest credit is due to Mr. Z. de Ferranti, who, unaided by any other engineer, has designed the whole of the works, from the buildings and his huge dynamos down to the mains, transformers, and meters.

1. *Industries.*

ELECTRIC TRAMWAY IN PARIS.

FROM time to time electric traction makes its appearance on the Paris tramways, but vanishes again after a brief spell of apparent success, for some reason not easily ascertained. The latest development of electric tramway work is an experiment which is being carried out on the line between Porte Maillot and the Barrière de l'Etoile by means of storage battery cars, which are very handsomely fitted up, and which have now been running for nearly two months. The battery is of the Faure-Sellon-Volckmar type, constructed by MM. Phillippart Frères, and consists of 144 cells, which, by means of a special switch, can be grouped in various ways so as to supply the current under different pressures, viz., 70, 140, 240, and 280 volts. The total weight of the car with 50 passengers on board is close upon 9½ tons, and the normal power required when running on the level, and at ordinary tramway speed, is 7 h. p.; but when starting and climbing gradients the battery is often called upon to deliver current at the rate of 20 h. p. The total capacity of the battery is 42 h. p. hours, so that the car can remain from five to six hours in service before having to be re-charged. The usual provision is made for charging batteries with the least possible loss of time. The motor is a Siemens dynamo placed under the car floor, and running at 1,000 to 1,200 revolutions per minute. The car is lighted by glow lamps fed from the batteries.—*Industries.*

ENERGY CONSUMED BY VARIOUS ILLUMINANTS.

THE production of light by any means implies the consumption ef energy, and this can be measured in *watts*, or at the rate at which this energy is consumed. A watt is $\frac{1}{746}$ part of a *horse-power*. It is a very convenient and sensible unit of power, and will in time replace the meaningless horse-power.

				watts.

The relative heat generation of these illuminants may be estimated from these figures.—*W. H. Preece, F. R. S.* Address as President Mechanical Science Section British Association, September, 1888.

.... THE engineer's electricity is a real form of energy; the speculative philosopher's electricity is a mere vague subjective unreality which is only a mere factor of energy and is not energy itself.—*W. H. Preece.*

.... MENTAL inertia, like mechanical inertia, may be defined in two distinct ways. Inertia is the resistance to motion, that is the English definition; but inertia is also the resistance to stopping,—that is the American definition.—*Professor Ayrton.*

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Bell Telephone Decision.—Meeting of the Medico-Legal Society.—Sale of the Waterhouse Co.—Fires Caused by Electric Wires.—Suit of Electrical Accumulator Co. vs. Julien Electric Co.—The Fourth Avenue Cars.—The Fulton Street Railway.—Increase of Capital Stock of Commercial Cable Co.—Assignment of Edwards H. Goff.—Experiments on the Elevated Roads.—Death of Herrick P. Frost.—Meeting of Board of Electrical Control.—A New Incandescent Lamp.

THE decision of the U. S. Supreme Court overruling the demurrer of the Bell Telephone Co., excited interest in electrical circles largely because an uninterrupted succession of victories had persuaded us that the Bell company's attorneys were invincible. The daily press, always on the popular side, unanimously expressed the hope that this decision would lead to competition in telephone service.

The Medico-Legal Society held its November meeting on the 14th ultimo, at the Buckingham Hotel. The committee appointed at the previous meeting to consider the best method for carrying out the new law providing for criminal execution by electricity, made a report recommending the use of a helmet, the current to enter the body at the top of the head, passing through the brain, and emerging at the back of the neck. They advise an electromotive force of 3,000 volts.

The Westinghouse Electric Co. has followed up its announcement of the control of the Sawyer-Man interests by the purchase of the Waterhouse company.

Defective insulation is alleged to have caused damage by fire to the extent of $10,000 at the Produce Exchange building, November 14th, and the day after a great commotion was caused at the Hoffman House, by crossed wires setting fire to the drapery of a large electrolier in the ladies' dining room.

The suit of the Electrical Accumulator Co. against the Julien Electric Co., has reached a final hearing. The suit was brought in January, 1882, to establish the validity of the patents controlled by the plaintiff. Professor George W. Barker, of Philadelphia, defendants' expert, has submitted an exhaustive report upon the state of the art at the time of the Fauré patent. Professor Henry Morton, and W. B. Vansize are complainants' experts. The defense is based upon the statement that an oxide of lead has been used as a depolarizer in a primary battery as early as 1863, and also in prior experiments of Dr. Van der Weyde and Charles F. Brush.

The storage battery cars of the Julien company, now running upon the Fourth avenue railroad, continue to attract a great deal of attention, and will doubtless do much toward stimulating general inquiry into the various methods of electric traction.

It is stated that the Bentley-Knight conduit will be laid at once for the Fulton street railway. The line will run from the Fulton Ferry across town to the west side ferries from Liberty to Chambers streets.

The Commercial Cable Co. has announced its intention of increasing its capital stock from $6,000,000 to $10,000,000. The prosperous condition of the company, and the demand for further facilities are alleged to justify this increase.

Mr. Edwards H. Goff, who retired from the presidency of the American Electric Manufacturing Co. to assume the management of the *Daily Graphic*, has made an assignment, and the control of the paper has passed into other hands.

The contract for the electric light plant for the imposing *Times* building has been awarded to the United States Electric Lighting Co.

A large amount of experimenting is being carried on with storage batteries with the object of increasing their durability and efficiency, and two new types are about to be placed upon the market.

Mr. H. R. Pierson has leased one of the main salesrooms of the telephone building, 18 Cortlandt street, where the Water Primary Battery Co.'s system will be shown.

Col. C. H. Haskins, of Milwaukee, stopped over in this city a few days upon his return from Europe.

The Manhattan Elevated Railroad has decided to try experimental storage-battery cars upon its switch connecting the Third avenue line with the Grand Central Depot at 42d street.

Notice has been received of the death of Mr. Herrick P. Frost, of New Haven, Conn. Mr. Frost organized one of the earliest telephone exchanges in New England, and retained an interest in a large number of local companies.

The Railway Cab Signal Co. has been experimenting on the Staten Island railroad for over a year, and now claim to have perfected their system.

The joint report of chief-engineer Kearney and electrical engineer Wheeler has been presented to the Board of Electrical Control. The sole cause of the trouble with the conduits is ascribed to the leaks in the steam heating pipes.

A new design of incandescent lamp has been patented by Mr. C. A. Backstrom, an expert employed by the Sprague company. A transparent support is used by which the filament is kept in position. The carbon is applied to the surface of the support in such manner that longer life is claimed than for the ordinary lamp.

An injunction was granted by the Supreme Court, November 19th, against the Board of Electrical Control, restraining the board from interference with the wires of the United States Illuminating Co., until a suitable subway is provided, and from the grant of privileges to the Metropolitan Telephone and Telegraph Co., the Western Union Telegraph Co., and the East River Electric Light Co. A motion to make the injunction permanent will be argued in a few days. The company claim to have been annoyed and discriminated against to such an extent that they have lost 150 subscribers on Broadway.

The Board of Trade and Transportation at its meeting, November 14th, appointed a committee to prepare a bill for the legislature regulating telephone rates.

NEW YORK, November 29, 1888.

PHILADELPHIA.

The Keystone Ordinance.—An Overhead License Refused an Electric Light Company.—Further Displacement of Gas by Electric Light in the Streets.—Hard Work by Telegraphers on Election Night.—Singular Accident to a Lamp Trimmer.—The Welsbach Incandescent Gas Light Company Offers Prizes for Designs of Shades and Globes.—Councils Still Engaged in Regulating Electric Privileges.—Lowell, Mass., Officials Visit Philadelphia to Inspect the City Electrical Department.—A Lecture by Mr. Sprague at the Franklin Institute.

THE Keystone Light and Power Co., whose ordinance giving it the right to lay its wires under a number of streets, has been the subject of some lively discussions in the electrical committee of city councils, astonished the committee recently by sending a communication signed by M. R. Muckle, Jr., as treasurer and secretary, protesting against the committee exercising any jurisdiction in the matter. After reviewing the futile efforts of the company to secure the desired ordinance, the letter said:—

> In presenting this ordinance to your honorable body we do most respectfully protest against all or any jurisdiction of your honorable body in this matter other than what is expressly given by the act of assembly under which the Keystone company is incorporated, to wit: Such regulations as your honorable body may adopt in regard to grades, or for the protection and convenience of public travel over the city streets. We do further most respectfully protest against any and all limitations, conditions or restrictions whatsoever being annexed to said ordinance other than such as are specified by the said act of assembly.

The subject was referred to a sub-committee of three, with instructions to consult the city solicitor and prepare an ordinance protecting the city's interests.

An ordinance allowing the Frankford Avenue Merchants' Electric Light Co. to erect overhead wires along the avenue from Norris street to Alleghany avenue was opposed by Messrs. Boyer and Adams, who held that the wires should go underground, and it went to a sub-committee.

A sub committee of the gas committee of councils met a few days ago to consider a proposal to replace the Siemens' gas lamps in the public squares with burners of improved pattern. Director Wagner suggested that the lamps should be removed and electric lights erected in their place, and a resolution authorizing the substitution was adopted.

Perhaps the hardest worked people on election night were the telegraph operators, who toiled at their instruments in the offices of the various companies, the club houses, newspaper offices, and even in private residences, from 7 o'clock on Tuesday evening until far into the morning hours of Wednesday. The Western Union company furnished the returns to about 65 clubs and a few private individuals throughout the city. Starting in at 7 o'clock P. M., by 3.45 A. M., Wednesday, 175 bulletins had been sent out averaging 50 words each. The service was the best ever given by the company, and the demand for the figures, both in the city and the surrounding country, was far greater than in 1884.

Superintendent C. C. Adams, of the Postal Telegraph Co., said that starting at 6 o'clock Tuesday evening and ending up about 3 o'clock Wednesday morning, that company handled about 200 words of outside telegraphic matter, which, with the Philadelphia returns, reached a total of about 250,000 words. Forty clubs and about 40 private residences in this city were supplied with the bulletins by this company.

Charles Borden, an electric light lineman, had an unusual experience a few days ago, which, however, saved him his life. He was engaged in replenishing carbon points in an arc light at Frankford avenue and Huntingdon street. He lost his footing at the top of the pole and fell headlong towards the pavement, but fortunately a protruding iron step caught in his clothing and held him suspended head downward for half an hour. He shouted for help, and was answered by Policemen Mason and Quick, of the 18th district. They were perplexed for a time to know how he could be removed from his uncomfortable and perilous position, but finally decided to procure a ladder and secure his

release. Ten minutes elapsed, and then the two policemen returned with the needed assistance. They climbed to Borden and carried him to the sidewalk, where it was discovered that the iron step, which doubtless saved his life, had lacerated his thigh. He was taken to the Episcopal hospital thoroughly exhausted.

The Welsbach Incandescent Gas Light Co. has made an offer of five prizes, ranging from $150 to $25, for designs for shades or globes adapted to the Welsbach incandescent light. The company is anxious to secure artistic designs for use specially in private houses. Messrs. Wm. G. Warden, Thomas Dolan, Henry C. Gibson, George Philler and William T. Carter, will act as judges in making a choice. All designs are to be submitted by November 26, next.

The joint committees on councils on the electrical and highway bureaus considered the proposed ordinance for the regulation of the occupancy of streets for electrical purposes. Lawyer Samuel B. Huey, counsel for the Penn and Edison Electric companies, drew the bill, which provides that the same privileges shall be granted to electrical companies as are enjoyed in making service connections with gas and water mains. The bill was approved, with a proviso that the privilege shall not extend beyond March 1, 1889.

A visit to this city was made a short time ago by the mayor and a number of other officials of Lowell, Mass. They came to inspect the workings of the electrical department. The visitors first called upon Mayor Fitler, and were then taken in charge by Chief Walker of the electrical bureau.

Frank J. Sprague, of New York, lectured a few nights since at the Franklin Institute, on "Long-distance Transmission of Power by Electricity."

PHILADELPHIA, November 16, 1888.

BOSTON.

The West End Railway Company.—Meeting of the Society of Arts.—Sale of the Newton Electric Light Co.—Explosion in a Conduit Man-hole.—The Agitation Against Overhead Wires.—The Electric Club.—The Flurry in the Stock Market Caused by the Supreme Court Decision in the Government Telephone Suit.—Quarterly Statement of the Erie Telegraph and Telephone Co.—Monthly Statement of the American Bell Telephone Co.

THE West End Railway Co. expect to have a few electric cars running by the first of December. The petition presented to the railroad commissioners met with no opposition, and the city authorities of Cambridge have recently given permission to construct and operate a surface electric traction system to the West End company. The privileges granted by the City of Cambridge oblige the street railway company to place and maintain an electric light upon each post, the posts to be protected by suitable iron or granite curbing at the base.

The 37th meeting of the Society of Arts, was held October 25, at the Massachusetts Institute of Technology. Mr. Charles A. White, of Boston, exhibited and described the eco-magneto watchman's clock. Mr. W. E. Gump, read a paper upon the Writing Telegraph, which closed with practical demonstrations of the method of operation of the system.

The Newton Electric Light Co.'s plant has been sold to the local gas company, at a price said to be $125,000. This action ends the contest between the two companies over the city lighting contract.

An explosion at the corner of Washington and Boylston streets in an Edison man-hole has been the subject of considerable discussion in the Boston papers. The heavy iron cover was hurled high in the air alighting upon and breaking the glass sidewalk in front of Sage's trunk store. District Manager Edgar's opinion is that the trouble was caused by sewer gas becoming ignited by a spark from the wires.

The agitation against overhead wires is being renewed with increasing vigor. Captain Flanders, superintendent of the fire alarm, reported at a conference of the heads of departments at the mayor's office that there were at least 400 miles of overhead wires in this city. Mayor O'Brien asked what would be the result if the legislature passed a law ordering all wires underground. Mr. Flanders replied that it would seriously interfere with the proper service of the wires. The council has authorized the special committee to visit New York and other cities for the purpose of examining the different conduit systems.

The Wednesday evening "informal talks" of the Electric Club have been continued. Recent papers were those of Mr. J. C. Wilson, upon the Police-Alarm System, and T. W. Sprague, upon Electric Applications to Mining in the West.

The board of aldermen have passed over the mayor's veto the order giving valuable privileges to H. E. Cobb, R. M. Pulsifer, and H. E. Chapman for constructing an underground conduit system. The franchise, however, is not exclusive.

The recent decision of the United States Supreme Court overruling the demurrer of the Bell company, caused a commotion in the stock market, the stock selling off to 187 from 207, but rallied later to 200. The heavy selling was largely due to a misapprehension of the purport of the decision.

The Erie Telegraph and Telephone Co. directors have declared a regular dividend of three-quarters of one per cent., and an extra dividend of one-half of one per cent., both payable November 12, to stockholders of record at 2 P. M. November 5, the stock books being closed from the latter date until November 12. The statement of operations for the quarter ended September 30 and the first half of the current fiscal year is as follows:—

September—	1888.	1887.	Increase.
Gross earnings	$168,361	$153,795	$14,566
Gross expenses	109,054	100,780	8,274
Net earnings	$59,307	$53,015	$6,292
Construction	8,847	12,350	*3,503
Balance	$50,460	$40,665	$9,795
Dividends	36,000	36,000	....
Surplus	$14,460	$4,665	$9,795

*Decrease.

The number of subscribers connected July 1, 1888, was 10,747; added during the quarter ended September 30, 285; total connected October 1, 1888, 11,030, against 10,299 October 1, 1887; increase in one year, 731.

The statement of the output of telephones by the American Bell company for the month ended October 20, and the fiscal year to date, is as follows:—

October--	1888.	1887.	Increase.
Gross output	4,140	3,689	451
Instruments returned	2,145	2,213	*68
Net output	1,995	1,476	519
Dec. 21 to Oct. 20			
Gross output	45,800	44,340	1,460
Instruments returned	18,947	22,028	*3,081
Net output	26,853	22,312	4,541

*Decrease.

BOSTON, November 17, 1888.

CHICAGO.

The Chicago Telephone Co. and the City Council; the Company Declines to Accept the Ordinance Reducing Rates; its Reasons Presented in a Letter to the Council.—Judge Blodgett's Decision Against the Cushman Telephone Co. in the Indiana Case.—The Cushman Company Petitions for a Re-hearing of the Infringement Suit Decided Last July.—An Electric Lighthouse on the Lake; The Fog Bell Worked by an Electric Motor.—Installation of a Baxter Motor.—The City Lighting Plant.—The Rapid Introduction of Motors on the Edison Circuits Expected.—The Chicago Electric Club; a Paper by Mr. C. C. Haskins.—Locomotive Engineers Ordered to Provide their Watches with Anti-Magnetic Shields; they Protest and May Strike.—Electrical Business Outlook.—The Van Depoele Company.—Professor Badt's Return from Europe; he accepts a position with the Western Electric Co.—Incorporations and Business Notes.

IT was mentioned in the Chicago letter of last month, that the city council had passed an ordinance for the regulation of the business of the Chicago Telephone Co. A new schedule of rates, which was the principal feature of the ordinance, reduced rentals from $125 per year to $95 the first year and $85 each succeeding year, or $75 on three years' contracts. It was the general belief that the company would not accept the ordinance. Predictions proved correct. At the city council meeting of November 12, a communication from the president and directors of the telephone company defining their position in the matter was presented. They attempted to show why it is that telephone service is more expensive in cities than in smaller places. It does not seem to be a difficult subject to grasp, but the Chicago company finds it necessary to combat the idea that "the telephone companies are the only concerns which sell higher at wholesale than at retail." The document is interesting to all telephone companies because it attempts to elucidate this point. The essential part of the communication follows:—

To improve their service and to give the public the best telephonic conveniences known to the art, we have expended over $1,000,000. As a matter of fact, all of our construction has been made upon the streets of the city with the express consent and often under the direction of the officers of the city.

October 15, last, the city council passed an ordinance defining the rights of the rights of the Chicago Telephone Co., in which ordinance they inserted a provision that said Chicago Telephone Co. shall not charge for the use of each telephone connected with its exchange more than $85 for each year subsequent to the first, and shall contract for three years' service with any one party at the rate of $75 per annum, which limitation prevents our acceptance of the ordinance. The present differences between the city and ourselves arose, we believe, on account of a misapprehension as to our rights in the city, the amount of free telephone service we render the city for these rights, and the fairness of the price we charge our patrons for the service rendered them, which misapprehensions we would like the opportunity to correct.

As to the first of these questions, we have already referred to our rights derived from the city.

As to the second, the city has, under its grants to the company, the right to demand certain free telephone service. This right is conceded by us, and the service given the city. After this engagement was entered into, one of your

citizens invented and introduced what is known as the police patrol system, for which we voluntarily made a special arrangement with the American Bell Telephone Co., whereby we have been enabled to rent you telephones for the use of the patrol system at a lower price than we furnish them to any other customer for similar service. Including the above rebate, with the exchange and private lines, which we are furnishing the city without any charge, we are making a concession of over $10,000 per annum in excess of the requirements of your ordinance.

A list of cities with the rental charged by the companies is presented, after which the letter continues as follows :—

In the ordinance passed October 15, the city undertakes to legislate upon the matter of rates to be charged by the telephone company, a subject which our counsel advise us is not covered by the city's charter, and that for that reason the ordinance is void.

This company is not disposed to stand only on its legal rights, but is willing to make a fair adjustment of the differences between us, for which purpose we will be pleased to discuss the questions with any committee to whom you may refer the matter.

It has been, and is, our policy and our endeavor to conduct the difficult business of this company honestly and with fairness to our subscribers. No effort or expense has been spared to secure the best mechanical devices, constructions, and operators.

We submit, with due respect, that we know of no good reason why this interest should be singled out by the city and weighted with burdens imposed on no other corporate interest in Chicago.

In estimating the fairness of our charges to the public, it seems to be generally forgotten that we pay more to a railroad to carry us 1,000 miles than 100; the grocer more for a barrel of sugar than a pound; more for an advertisement in a newspaper of 100,000 circulation and published daily than of 10,000 circulation, with only a weekly edition. We say it seems to be generally forgotten, because we are denied an application of the same principles which govern in the cases above mentioned. It is unquestionably true that smaller places charge less per annum to each subscriber than we do, but it is equally true that less is furnished, and that each service or "connection" costs more in those places than here. The average cost of our service to the subscriber last year in this city was a fraction under two cents per connection.

The only other means of communication which approaches this in cheapness is the postal-card, where a brief question and answer may pass between two people for two cents, using at least 12 hours' time.

The finance committee of the council subsequently endeavored to bring about an adjustment of the controversy but failed. The president of the telephone company offered to pay as consideration for the corporate privileges 2½ per cent. of the gross income, but he refused to make any reduction in rentals to subscribers. The council is rather inclined to test the matter in the courts. The legal department is confident that a decision affirming the right of the city to regulate charges can be obtained from the Supreme Court.

In the suit brought by the Bell company against the Cushman Telephone Co. for infringement for operating telephone exchanges in Indiana, Judge Blodgett has handed down a decision in favor of the plaintiff corporation. In his decision Judge Blodgett says :—

Defendants are engaged in furnishing telephone service and operating exchanges in several cities in Indiana, and insist that an injunction should not be granted on this motion, because a few years since the complainant's grantees or licensees established telephone accommodations in some, if not all, of these cities, but withdrew therefrom after the passage by the legislature of Indiana of an act limiting the rates of charges for telephones and for telegraphic services.

I do not think the fact that the complainants, licensees, or grantees have withdrawn their telephonic accommodations from these cities furnishes any excuse or defense for the infringement of these patents by these defendants. The law gives the owner of a patent the exclusive right to the use of the device covered by his patent, and the rule that because the patentee or owner of a patent cannot agree with those who wish to use his device as to the price to be paid for such use, authorizes another to pirate upon the patent with impunity, would be destructive of patent property.

In reference to the validity of the Indiana statute, the court says :—

Counsel for the defendants insist that the main question involved in this case is the validity of the Indiana statute regulating the charges of telephone service, but I do not consider that question involved in this motion. It was stated on the argument of this motion, and I doubt not truly, that this question is in the way to be presented at an early day to the Supreme Court of the United States, which is the proper tribunal to pass upon it. But it would be strange indeed if, where A is the undisputed or adjudged owner of a patent which B wishes to use, but B is not willing to pay the amount demanded by A for such use, therefore C can infringe the patent and supply B with infringing machines and not be restrained from so doing, when the validity of the patent and infringement are clear.

The Cushman company took the position that Judge Blodgett had decided in the case of Hoe against Knapp, that a patentee who did not put his invention into use was not entitled to an injunction. On this point Judge Blodgett found as follows :—

I think, however, that the case there made was another and widely different one from this, runs the decision. There the patentee had never made a machine nor put his patent into use; he had simply locked it up, so to speak, and kept the public from the benefit of it. Here the patentee has put his patent into extensive use and is receiving a large income for such use at rates agreed upon between the owners of the patents and the users; so that this complainant does not stand as the complainant did in the case cited.

The Cushman Telephone Co., of Chicago, filed a petition November 2, for a rehearing in the general infringement suit, in which it was beaten at all points by the Bell company last July. The petitioners allege that in his decision Judge Blodgett misapprehended material facts in proof; that he failed to consider many important facts; had drawn conclusions not warranted by facts, and had erred in the application of the law. It is also alleged that further material evidence will be forthcoming.

The first electric lighthouse on the lakes is now to be seen in Chicago. The installation is at the water-works crib, half a mile north-east of the North Side pumping station. The lighthouse is 70 feet in height, and the lamps are surmounted by a circular glass lantern. The lighting apparatus consists of 24 32-c. p. lamps, mounted with a circular reflector. The light can be seen eight miles away. The fog bell is 600 pounds in weight, and is struck by a 24 pound hammer, which is raised and dropped eight times a minute by a revolving cam connected to a quarter horse-power electric motor. The motor and lamps are operated by switches in the dynamo room of the water-works. The current is conveyed to the crib by five lead covered cables.

The Chicago department of the Baxter Electric Motor Co., has installed in Augustana College, at Moline, Ill., a one horse-power motor for blowing the organ in the institution. The mode of operating the motor is extremely simple. The motor switch is connected to a small cable, one end of which is attached to the movable part of the bellows. To the other end is fastened a weight. As the bellows are filled with air the weight will close the switch. As the bellows are emptied the cord is drawn in the opposite direction and the motor is set in operation. The motor is on an arc circuit.

It is now predicted that the city electric light plant will be put in operation on Christmas day. It was prophesied that the work would be completed weeks ago, but one obstacle after another was encountered which necessitated the postponement of the opening day. The city officials say that everything is now in such satisfactory condition that they feel warranted in making another prediction.

With the extension of the Edison circuit in the city comes a widened field for the employment of motors. Unless predictions fail, installations of motors will soon be numerous. The Edison company has reduced its charges for power service. It is more than probable that motors will be employed in running high speed elevators in several new buildings.

At the meeting of the Chicago Electric Club, October 29, C. C. Haskins read a paper on "Universality of Vibrations." The subject was thoroughly discussed by Mr. Haskins, and his treatment of it was full of interest and suggestion.

The locomotive engineers of the Northwestern railroad have been ordered to provide their watches with anti-magnetic shields. They are protesting, and it is asserted that if the order is rigidly enforced a strike may be declared.

The business outlook for the electrical trade in Chicago seems to be most hopeful. Orders in all departments are large, and less business is transacted for honor. The fall trade has been large and the outlook for the winter is encouraging.

The Van Depoele company, of Chicago, has completed its first incandescent dynamo, and has sold it to the Ferracute Machine Co., of Bridgeton, Conn. It is a 200 light machine. Hereafter incandescent lighting will form an important feature of the Van Depoele company's business.

Professor F. B. Badt, who was formerly connected with the Chicago office of the United States Electric Lighting Co., has returned to the city after a six months' visit in Europe. He has accepted a position with the Western Electric Co.

The Gas and Electric Light Co., of Alton, Ill., has been incorporated. The capital stock is $60,000, and the incorporators are Alva E. Campbell, John Watt, and Levi Davis, Jr.

The Decatur (Ill.) Electric Street Railway Co., has been incorporated by E. T. Martin, C. M. Barclay, and F. Sargent. The capital stock is $100,000.

The Cutting Electric Alarm Co., of East St. Louis, Ill., has been organized with a capital stock of $8,000, by W. H. Cutting, B. C. Graham, and B. Gratz.

The Consolidated Electric Light and Power Co., of Aurora, Ill., has been incorporated with a capital stock of $50,000. The incorporators are, I. B. Copley, Howard Knowles, and I. C. Copley.

The Shaw Electric Crossing and Advance Signal Co., of East St. Louis, Ill., has been incorporated. Capital stock, $1,000,000; incorporators, W. P. Shaw, A. X. Mackey, and John B. Livingston.

CHICAGO, November, 20, 1888.

POINTERS.

. . . . PUTTING a conservative drag on the wheels is a very good precaution to take when going down hill, but it is out of place in the up-hill work of progress.—*Professor Ayrton.*

. . . . 110,000 miles of cable have been laid by British ships, and nearly £40,000,000 of British capital has been expended by private enterprise in completing this grand undertaking. A fleet of 37 ships is maintained in various oceans to lay new cables, and to repair breaks and faults as they occur.—*W. H. Preece.*

. . . SOME people fancy because the answer to that oft repeated question "What is electricity?" not only cannot be given exactly, but can only be guessed at in the haziest way, even by the most able, that therefore all electric action is haphazard. As well might the determinations of a ship's latitude at sea be regarded as a mere game of chance, because we have not even a mental picture of the ropes that pull the earth and sun together. —*Professor Ayrton.*

LEAD ENCASED CABLES.

[100.]—I HAVE read with much interest the letter of Mr. David Brooks (99), printed on page 543, your November 1st issue.

Some time ago, about two and one half years, the electric light company in which I am interested required a cable for crossing a river. I made some inquiries at that time regarding the best cable to be used for that purpose, and found that lead covered cables with paraffine insulation had given good results where numerous other forms of cables had failed. My company ordered such a cable, armored with iron wire, and it has given good results. There has been no failure of the cable, and to all appearances it is as good to-day as when first laid. I happen to know that in three other cases at least this same style of cable has given equally good results, for a period of time longer than that for which I have used the cable.

I am about to order some more electric light cable for another location. I do not know much about the theory which Mr. Brooks talks about, but on the other hand I seem to have the advantage of him in the little experience I have had with lead encased cables.

Don't you think I am safe in being guided by my experience?

LITERATURE.

REVIEWS.

Materialen für Kostenvoranschläge Electrischer Lichtunglagen. VON ETIENNE DE FODOR. Wien, Pest, Leipzig: A. Hartleben's Verlag.

HARTLEBEN'S Electro-technische Bibliothek has found eager readers in this country because its volumes contain so much that is of importance to the practical electrician. The publishers of the series are fortunate in securing writers who are successful in apprehending and meeting the wants of this class. This thirty-ninth volume is no exception in this particular. In the 224 pages which are devoted to the enumeration and description of the materials on which estimates of the cost of electric lighting plants are based, there is little that is superfluous, and yet the lists of apparatus appear complete.

Considerable attention is given to a description of the Edison "three-wire" system. As the estimates of the cost of such a plant have to be modified to suit its peculiar conditions, such a description is, perhaps, not unnecessary. The first part of the book is, in a measure, preliminary and is descriptive of dynamos, storage batteries, incandescent and arc lamps, and the various other parts of an electrical equipment. For the most part the matter is sufficient and at the same time concise; but the information regarding dynamos is somewhat meagre in respect to the number of manufacturers whose machines are described.

The types of the Edison, Gramme, Siemens, Halske and a few others are given in full; but several kinds are conspicuously absent. The part concerning cut-outs and switches is particularly good, and is copiously illustrated.

The main part of the book is devoted to lists of apparatus for different kinds of plants. Here is shown considerable care in details. In the specifications for a central station, there is given, not only the aggregate of hours of lighting for the year, but tables of hours for each month.

On the question of comparative economy in the "three-wire" and alternating current systems, the author decides in favor of the latter for distances above 3,000 feet. For less than that he recommends the former. The question of the comparative economy of several small steam engines and a single large one for a central station, is settled in favor of the former—a conclusion that experience in this country seems to justify. The subject of isolated plants is pretty thoroughly treated. The theater, the man-of-war, the hospital, the concert garden, the railroad passenger coach, and many kinds of factories are all equipped (on paper) with the requisites for electric lighting.

The book can be recommended to the student in electrical engineering, as giving him an idea of one of the problems he will have to solve; to those contemplating the installation of an electric lighting plant, as showing them what expenses they will have to meet; and to the electrician, for whom all tables and data such as are here collected have their use.

RECENT PUBLICATIONS.

The Steam Boiler Catechism; A Practical Book for Steam Engineers, and for Firemen, Owners and Makers of Boilers of Any Kind. By Robert Grimshaw, M. E. New York: *D. Van Nostrand and Practical Publishing Co.* 16mo., cloth, 402 pp. Price $1.00.

Die Erzeugung und Verteilung der Elektrizitat in Zentral-Stationen. Von Dr. Martin Krieg. Band II. Magdeburg, 1888. *A. & R. Faber*, sm. 8vo., paper, 371 pp.

CATALOGUES AND PAMPHLETS RECEIVED.

Pocket Hand-book—Standard Underground Cable Co. The makers of electrical cables and wires vie with one another in the issue of manuals containing a variety of useful information in addition to their trade announcements and price lists. The recent hand-book sent out by the Standard Underground Cable Co. supplements its lists of wires and cables, with prices, by 25 pages of useful information, bearing, for the most part, upon matters relating to electric conductors. A brief telegraphic code specially prepared for use in business correspondence with the company, is followed by a series of useful tables, and rules, interspersed with many facts and items convenient for the practical worker to have at hand. Among the handy tables are the following:—Fractions of an Inch Expressed in Mils (from $\frac{1}{64}$ to $\frac{1}{2}$ inch); Feet in Decimal Parts of a Mile; Wiring Table for 50 Volt Lamps, 2% loss; Melting Point, Specific Gravity and Conductivity of Various Materials; Table of Weights and Measures—besides the usual wire gauge tables. The diagram illustrating the circular mil on page 35, will be found useful as a sort of object lesson, by linemen and others not fully conversant with the somewhat confused nomenclature employed in practice, and who desire to understand the mutual relations of the various terms used. The hand-book concludes with working directions for placing, splicing and connecting electric cables.

The Seafert Electrical System, Light and Power. A pamphlet thus entitled reaches us from Chicago, and is issued by William Seafert & Co. What this "system" is does not appear in the pages of the circular, but what it is going to do is set forth with much confidence. Some particular mode of regulation for dynamos appears to be the basis of the Seafert system. The reader is told how the regulation is *not* accomplished, at considerable length, but, as to how it is done has to content himself with the information that "the simple tilting of a delicately poised lever effects the entire regulation without loss or waste of energy." Further quotations are the following:—"The principle is adapted equally to the direct or alternating current." "The energy required in the external circuit is made the limit of output in the generator." "The principles underlying the Seafert system make it possible to dispense with all devices which absorb current energy, but yield no equivalent in useful work." Everybody interested in electrical distribution will readily agree that "this is what we long have sought, and mourned because we found it not."

We are in receipt of a copy of the Report of the Special Public Lighting Committee, of Detroit, Mich.,-sent us by Mr. Fred. H. Whipple, who compiled the information by direction of the committee. The report contains much matter of interest upon the following subjects:—"Cost of Public Lighting in other Cities by the Rental System," "Cost of Lighting in Cities which Own and Operate their Plant," "Methods of Electric Street Lighting," "Underground Lines."

The report includes letters received from the executive officers of a large number of companies who have tried various systems and devices, and the results given are both interesting and instructive. Mr. Whipple has also made use in his report of the proceedings of the National Electric Light Association at several conventions—printing several papers relating to underground work, with copious extracts from the discussions of the Association.

A Directory of Electric Arc Lighting Plants in North America, issued by the National Carbon Co., of Cleveland, Ohio, contains in 92 octavo pages, a convenient list of arc plants arranged by states, territories and provinces alphabetically. Lamps are classified as commercial, street and isolated. The National Carbon Co. request all who are interested in arc lighting to send them full information in the way of correction or addition, for use in a subsequent edition of the directory. They desire it to be accurate and complete.

POINTERS.

.... IT is so easy to be wise when criticising the past, so difficult to be wise when prospecting the future.—*Professor Ayrton.*

.... PEOPLE are singularly callous in matters affecting their own personal safety; they will not believe in mysteries, and they ridicule or condemn that which they do not understand.—*W. H. Preece.*

.... THE means of ready intercourse and of communication, and the means of easy travel, are all due to the application of science by the engineer. Is not, therefore, his profession a beneficent one?—*Sir Frederick Bramwell.*

.... I ONCE ventured to predict that unless some substantive improvement were made in the steam engine (of which improvement as yet, we have no notion), I believed its days, for small powers, were numbered, and that those who attended the centenary of the British Association in 1931, would see the present steam-engines in museums, treated as things to be respected, and of antiquarian interest to the engineers of those days, such as are the open-topped steam cylinders of Newcomen and of Smeaton to ourselves. I must say I see no reason, after the seven years which have elapsed, to regret having made that prophecy, or to desire to withdraw it.—*Sir Frederick Bramwell.*

.... I COULD write you volumes on the improvements which I find made, and making here, in the arts. One deserves particular notice, because it is simple, great, and likely to have extensive consequences. It is the application of steam, as an agent for working grist-mills. I have visited the one lately made here. It was at that time turning eight pair of stones. It consumes 100 bushels of coal a day. It is proposed to put up 30 pair of stones. I do not know whether the quantity of fuel is to be increased. I hear you are applying the same agent in America to navigate boats, and I have little doubt, but that it will be applied generally to machines, so as to supersede the use of water ponds, and, of course, to lay open all the streams for navigation —*Thomas Jefferson.* Letter to Charles Thomson, dated London, April 22, 1786.

NEWS AND NOTES.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

MEETING OF NOVEMBER 13, 1888.

THE American Institute of Electrical Engineers met on the 13th of November at 8 P. M., at the College of the City of New York. Mr. Ralph W. Pope, secretary, announced the receipt of a letter of regret from the president, Mr. Edward Weston, saying that he would be unable to be present.

On motion of Mr. T. C. Martin, Captain O. E. Michaelis was chosen chairman for the evening. Captain Michaelis, on taking the chair, said :—

Gentlemen, I am very much obliged to you for this mark of your kindness. At this early meeting of the current working year, we may especially congratulate ourselves upon having papers presented to us in so desirable a manner. We have here, perhaps for the first time in our history, an opportunity of illustrating papers properly, and I am sure we are all very thankful indeed to the officers of the college who have extended these facilities to us. As is our custom, no business will be transacted this evening except the reading of the papers and the discussion thereupon. The first paper of the evening is on "The Geyer-Bristol Meter for Direct and Alternating Currents," which the author will read. It is needless for me to introduce this gentleman to you. He is a graduate of this institution, and for the past 20 years has been pupil and coadjutor of Professor Morton, of the Stevens Institute.

Professor Geyer then read his paper (see page 571), and made the following remarks in addition :—

The compound bar in its simplest form consists of two strips of metal soldered for their whole length and flatwise, these two metals having different coefficients of expansion. In the bar I have, the metals are brass and steel. The brass expands more than the steel, consequently the bar bends, becoming convex on the side of the brass. Thus I have here a bar which is practically straight: I heat it for a moment and the bar is very notably bent. If such a bar were heated by electricity it would also bend. The disadvantage of an instrument constructed in this way would be that it would also be a thermometer, and to make it simply a current meter would require the introduction of troublesome corrections.

I will just for a moment call your attention to the instrument. You will see it has been recording for the time you have been here. By the kindness of the authorities here I have been furnished with current as you see, which here supplies a rack of lamps, and as I turn the lamps off and on you can notice that the pointer gradually goes down or up, leaving its record. The pointer does not respond instantly to changes of current, but as in actual use this record is spread over days, and in fact probably over weeks and months. This, I think, would not be a serious inconvenience. The clock that we have here at present causes that dial to rotate once in 12 hours. Of course, we might have a clock rotating faster or more slowly. If it had been convenient, I should have gotten one where the dial moved much more rapidly.

The Chairman—Gentlemen, I am sure we are all very grateful to Professor Geyer for his clear and able exposition. The subject is now open for discussion. It is understood, I hope, that the discussion is not limited to the members of the Institute, and that we would be very glad to hear from any of our friends who are with us this evening.

Professor Mayer—I was going to ask one question merely to illustrate farther what I have heard, that is as to the linear quantity separated from the plane.

Professor Geyer—I have not estimated or tried to measure exactly what that quantity is. Our idea is to bring the wire of course very close to the centre line of the strip, but of course not going sidewise with the centre line of the strip. I have several bars here finished right off, passing the current through which the gentlemen are at liberty to examine. If you will give me just a moment, I might illustrate by drawing the relative position of the strip and wire. This (making a sketch) represents the strip. Let this represent the wire and then let this part be insulation. I have made it here unnecessarily thick. Then we have another portion of the strip. This then represents the strip, this represents the cross-section of the wire. This insulation I have made unnecessarily thick. That portion of this strip which has been driven to the rear side will, when the dies are brought down, pinch it on that side, whereas that portion of the strip will pinch it on the other side. I might state in an incidental way that these pieces of the strip are made unequally wide by the dies, so that as it runs down bringing pressure they are stretched up one a little more than the other, showing the wire outside of the centre.

Dr. Wheeler—I would like to ask Professor Geyer what is the effect of changes of atmospheric temperature on the instrument.

Professor Geyer—We have experimentally tried to find out whether atmospheric changes of temperature did affect it by taking it in the winter time from an ordinary heated room into a hall-way or passage-way where the temperature was below freezing, and then passed the same current as current by another instrument through it without being able to detect any difference in the reading. It is the difference of the temperature in the two bars which counts, not the actual temperature of either one.

Mr. F. B. Crocker—I would like to ask Professor Geyer if the moisture in the atmosphere had anything to do with it. The same question arises in regard to the Cardew voltmeter. I have never heard that question answered. Now every moist day, for example, this bar which is intended to get hot, loses its heat more quickly than it does on a very dry day. In other words, would the difference in temperature be greater on a dry day than on a wet day?

Professor Geyer—On that point we have not made any experiments. I should judge from general principles as it is simply the difference of temperature between the two bars, that the case would be analogous to the case that I mentioned before, putting the instrument into the warm room and then into the cold room; the moisture in the atmosphere if it has any effect, being simply only equivalent to increased heat or increased cold around the instrument. Experimentally I could not say what the results would be, although I should imagine they would be negative.

Mr. Carl Hering—I would like to ask whether it would make any difference with this instrument whether the current were direct or alternating.

Professor Geyer—It would make no difference whether the current were direct or alternating. What we measured is the heating effect of the current. We say an alternating current is equal to a continuous current for all practical purposes when it produces the same heating effect.

In answer to a question by Dr. Van der Weyde, Professor Geyer said :—

The instrument as shown here is intended only as an ammeter, although we believe a volt meter can be made. In this case it is necessary to introduce very high resistance. That we think we can accomplish by causing the current in one of the parts not simply to come down but to go back and forward a very great number of times. Thus instead of the wire which grows hottest in our present arrangement, we take a very fine wire—which of course it must be to make a voltmeter of—and bend it backward and forward a great number of times, and then lay that as a flat disc upon the other strip. (Illustrating.) The other strip having the current passing through it or not passing through it as may be desired.

I found it would be heated anyhow by its proximity to the wire here; but there would be no difficulty, of course, in passing the current through this strip in addition to passing it through, zig-zag, back and forward.

Dr. Van der Weyde—The objection to using the principle of expansion by heat as a voltmeter, is that currents of a very small number of amperes have no heating effect. It is the amperes which cause the heat; the electromotive quality does not. For instance, in the old fashioned friction machine we have plenty of force; the electromotive force is very great. Professor Mayer, in a lecture at the Stevens Institute, demonstrated that the number of volts of a static machine went up into the thousands. A volt meter based on the expansion principle has a very limited range, and in fact it is but a metallic thermometer calibrated for volts. If you calibrate it for amperes it may be very correct. There is no doubt of it because the amperes cause the heat.

Professor Geyer—Whether we say that it is the current that heats the wire or the electromotive force that heats the wire, to my mind is a mere question of words, because we ordinarily understand that it is the electromotive force that makes the current, so we could say the current heats or the electromotive force heats.

The question as to whether a volt meter will record so many volts, or so many volts, is to my mind simply a question of proper adjustment of parts. Thus, for instance, at the Stevens Institute we had occasion last summer to measure directly the electromotive forces of a Westinghouse alternating machine. We wanted to measure if possible directly without any multiplying devices, volts say from 10—go up to 500—we therefore constructed a volt meter sufficiently long—in fact it was two stories high, and we had no difficulty whatever in getting very large deflections for 10 volts—that is as low as we cared to go, and we made our pointer go around nine times for 500 volts. To make no mistake in counting the nine turns we had a secondary dial, which, as on a common clock, rotated one division for each revolution of the other dial.

Mr. C. O. Mailloux—I would like to ask Professor Geyer what is the rule or law, or function of getting the deflection of the strip with the rate of current.

Professor Geyer—In some respects it may be unfortunate that the deflections are not proportional to the currents. It would hardly be expected. As we all know the heating effect varies as the square of the current, so if I double my current I have four times the heat produced, but then the bars will lose their heat much more rapidly when they are at a higher temperature. The deflections are not then as the square of the current, but as some intermediate function. I have plotted out some curves, and if I

had thought of it I might have drawn them on the board. I have not a curve here, but I might represent it, making a guess at it. Let the horizontal line (referring to a sketch) represent amperes, and let the vertical line represent deflections. If there were no increased loss of heat due to increased radiation from increased temperature, then, of course, our curve would be one rising quite steeply, and of course if the deflections are proportional to the current, our curve would be a straight line. As a matter of fact it is a curve between a straight line and the curve which rises as steeply as the amount of heat due to the law of radiation would require.

In reply to a question by Mr. Walcott, Professor Geyer continued :—

It can be seen by noting the relative distance of the concentric circles what the rate of increase is for increased current. You will at once notice at the outside of the disc that the distance between two concentric curves is greater there, that the instrument grows more and more sensitive as the amount of current on it is increased.

Mr. Crocker—I would like to ask Professor Geyer one question, which I think has an important bearing on all meters, and that is as to the amount of current consumed by it compared with the amount of current that it measures—that is to say, the efficiency of the meter. I think these meters working by the heat produced —for example Professor Forbes' meter, and to a certain extent the Cardew meter, consume rather a large quantity of current in proportion to the current that they measure. For example, when 10 lamps are in circuit—we say 10 amperes—I would like to ask Professor Geyer what the drop over the meter would be in volts.

Professor Geyer—I agree with Mr. Crocker that the question of resistance is a very important one indeed, and we have aimed to keep the resistance of the ammeter low. The resistance of the bars which are here exhibited, is about .06 of an ohm. We believe it could be brought much lower, possibly by using other metals. Probably the length of the bar might also be much shortened. When I tell you the resistance of the instrument is so much, you can calculate at once for any given current the loss of energy in the meter.

Dr. Wheeler—What is the ampere capacity of that .06 strip?

Professor Geyer—That strip will carry currents up to 20 amperes and possibly greater. We have not urged it beyond that point. It can be made to any capacity by making the cross-section of the pieces greater.

In the Cardew instrument, of course, great resistance is not an objection. It has always to my mind been one objection to the Forbes' meter, that it consumes relatively a large amount of energy. He uses a very small proportion of the heat produced to operate a little windmill. We may be said to use the whole heat produced.

Mr. Walcott—With regard to the volt meter which was drawn on the board, the reason why I asked my question was because it would require considerable length of wire, and I should judge the self-induction would be very high. That seems to be the trouble with using a straight wire.

Professor Geyer—I think if the wire were wound zig-zag, the self-induction would, for that very cause, be eliminated.

Dr. Moses—I regret to say, gentlemen, that I came late this evening. There are one or two questions that may be a little at random, but they are simply through ignorance, not having heard the earlier part of Professor Geyer's lecture. Is there any superior advantage in having different radiating areas of the same metal over different radiating areas of different metals?

Professor Geyer—The great point is that we have two strips whose co-efficients of expansion are equal, so that simple atmospheric changes shall not cause the bar to deflect. If then you select two different metals, which however have the same co-efficient of expansion, it will not alter the action of the instrument. The object of getting more radiating surface is to get a greater difference of temperature between the one conductor and the other conductor.

Professor Mayer—The whole question resolves itself into this: The instrument comes very soon into equilibrium, although we may have different metals, so that it takes three times as much heat to heat one as the other. The radiation of the instrument will depend entirely on the difference between the plate and the surrounding surface; so that this question does not enter into consideration, in reference to the action of the instrument, so far as I can determine.

Dr. Moses—One farther question. Do you believe it is possible to keep the surface at the same equal degree of polish, and in that way to be able to get equal ratios of radiation? Take german silver; the oxidation that will take place upon it from the increased radiating area of one side, may in that way affect its accuracy after a while, may it not?

Professor Geyer—I think it would affect the rate of variation to a slight extent. We propose to use such a cross-section that the wire shall never lose its polish from simple heat generated in it. It would thus only lose its degree of polish gradually if subjected to severe treatment from without—say strong acid fumes. Ordinary atmospheric changes do not seriously affect german silver.

Dr. Moses—In the case of alternating currents have you considered the electric density, so to say, of the conducting body in relation to the differences of areas. That is a question that has recently been brought forward. Have you had time since its suggestion to look into the matter.

Professor Geyer—I must confess my ignorance, and ask the Doctor to explain what he means by electric density. Then perhaps I shall be able to answer.

Dr. Moses—I mean by that the fact that in conductors of different areas of cross-section there have been found to be certain parts of them that by an electromotive force set up within the body of the conductor itself it has been found to be like the central part of rods in mechanics in strains, that do not have the same ratio of conductivity owing to the sudden alternations of the current; the current not seeming to be able to permeate as it were to the centre. This difference in area might in some way or other affect the amount of current that would pass over the conductor wire and surface, and in that way somewhat affect the heat radiation.

Professor Geyer—I thank the doctor for his clear explanation. I can only answer it as far as this—that I have lit up lamps with a continuous current and noted the deflection of the instrument, then heated them up to the same degree of brightness as measured on the photometer, and noticed the deflection when they were lighted by an alternating current of 16,000 alternations per minute and could notice no difference in deflections.

The Chairman—The chair hears no further remarks, and we will, therefore, proceed to the next subject.

We are fortunate in having with us this evening a distinguished gentleman from abroad, a prominent mathematician, a well known contributor to that peerless European technical journal, *La Lumière Electrique*, and a gentleman who has an important official connection with the electrical department of the forthcoming Paris exhibition.

He will exhibit to us one of his own many inventions, an invention that I know will engage the earnest attention of a New York audience, because I may call it in the vernacular an apparatus for dispensing with cranks.

I have the pleasure of introducing to you Mr. Abdank-Abakanowicz, of Paris.

Mr. Abdank—Mr. Chairman and Gentlemen, before I begin I must crave an indulgence. I am only a beginner in knowledge of the English language, and my vocabulary has only a few words, and it is the first time that I have spoken in public in your language.

Mr. Abdank then read a paper on "The Abdank Magnetic Call and the Abdank Integraph." (See page 572.)

The Chairman—I think we will all agree that Mr. Abdank has given us a great deal of information in a very brief time. The subject is now open for discussion, and as we have with us a number of distinguished college professors, I would advise that these gentlemen be requested to open the discussion. Will Professor Geyer favor us with any remarks?

Professor Geyer—I would say that the chairman has made it difficult for any one to reply, for he has called the gentlemen distinguished, and it looks very egotistic to get up first.

The Chairman—The gentleman was called upon by name. He is relieved from the charge of immodesty in that respect.

Professor Geyer—I would just like to ask one question, in reference to one of the experiments the picture of which is on the middle blackboard, the current being an instantaneous current, whether it was attempted to make any corrections for the self-induction of the galvanometer coil. As I understand it, the current was just a momentary current.

Mr. Abdank—The current was relative to the period of oscillation of the needle.

Professor Geyer—What I meant was whether the current really had time to develop its strength as to its electromotive force.

Mr. Abdank—The difference would be small.

Professor Geyer—I was more particularly interested in the subject because I had somewhat analogous experiments made under my knowledge, where it was attempted to measure the current of the electromotive force of an alternating machine where the alternations took place at the rate of 16,000 a minute, and it was there done by causing a condenser to be discharged and then at pleasure discharge it also through a ballistic galvanometer.

Mr. Walcott—Having been for some time interested in the study of integrating machines of various kinds, and having invented some myself, I can say that I never have seen anything which will approach this instrument. The ordinary type of integrating machine which Mr. Abdank has spoken of will simply give a reading at the end of a given time—simply a single reading. We are all familiar, that is, all who have given any study to the subject at all with the apparatus of Professor James Thompson, Sir William Thompson's brother, which will integrate any expression involving a single variable. It is simply a disc and a sphere in a cylinder. The distance of the point of contact of the sphere from the centre of the disc will represent the variable quantity—that is the function, and if this distance can be

made to follow any required law of motion and that point of contact of the disc is transmitted to the circumference of the cylinder which is uniform the whole length, it is evident that the motion of the cylinder is proportional to the distance of the sphere from the centre of the disc. This apparatus will also—that is, a combination of several of them—will also integrate differential equations; but I never heard of any apparatus, I do not think there is any like this one we have seen to-night, which will trace out an integral curve, one curve, the ordinates in which are integrals of the ordinates in the other curve, and I would be very much obliged to Mr. Abdank if he could give us the principle of this machine. Has he any printed description of it?

Mr. Abdank—I am writing out a description of the apparatus for a paper, and perhaps that will answer the gentleman's purpose. It will be published shortly.

A Member—I would like to say in behalf of Mr. Abdank, that one of the features of that instrument besides tracing the integral curve, is that it can be used for solving numerical equations which, I understand, cannot be solved algebraically—equations of a high degree, 4th, 5th and 6th degree. The instrument will trace out a curve the dimension of which will give the values of equations of high degree—2d, 3d, 4th, 5th, 6th, and so on.

Mr. Walcott—Does that give all the real roots in one curve?

Mr. Abdank—Yes.

Professor Mayer—If the machine will do that it is a marvelous production of ingenuity and science. Charles Babbage, of England, gave his whole life to making a calculating engine. After he had perfected his difference engine and the British government would not supply him with means of bringing it out, he invented an analytical engine, of which you will find a description by the only daughter of Lord Byron, Lady Lovelace, which machine did just what this does. The construction of it would be so difficult that Babbage had not the means of bringing it out. If a machine so simple in its construction will do that, I can see that it is the most marvelous production of this age. I would like very much to understand it. Of course, I only see it there and I know nothing of the principle of it.

The Chairman—I understand, Mr. Abdank, to put it in plain language, for instance, in solving any equation of the second degree the instrument would describe a conic section and so on, the cessoids and higher curves according to the nature of the equation.

Mr. Abdank—Yes. (The speaker then put an equation on the black-board and further illustrated the operation of the integraph by example.) With respect to the calculating machine of Mr. Babbage—I know that machine very well. My instrument acts in a different way. The machine of Mr. Babbage is only an arithmetical machine. It has nothing to do with differentials.

After the foregoing discussion, Mr. Abdank exhibited the Melotrape and the Melograph of Mr. Carpentier, very ingenious contrivances for the automatic performance of music on the piano-forte, or similar keyed instruments, and for the automatic recording of improvisation on such instruments. At the request of Mr. Abdank, Mr. Carl Hering, of Philadelphia, explained the principles and mechanism of the machines, after which the Melotrape was operated by Mr. Abdank upon a piano-forte. A variety of selections were played, from the works of both classical and modern composers, to the great pleasure and interest of the audience.

Before adjournment, the thanks and congratulations of the Institute were voted to Mr. Abdank for his painstaking and instructive papers. The authorities of the College of the City of New York were also cordially thanked for their courteous hospitality.

WHAT SOME PEOPLE THINK OF THE ALTERNATING SYSTEM.

EDISON ELECTRIC LIGHT CO.
16 & 18 Broad Street,
New York, September 27, 1888.

To the HON. GEORGE F. EDMUNDS,
United States Senate, Washington, D. C.

Dear Sir:—I have been recently advised that the system of electric lighting now in use in the United States Senate Chamber is supplied by what is known as the "Alternating current," by which a very dangerously high pressure current is generated by the dynamo, distributed through the wires in the Senate Chamber, and reduced in pressure by the intervention of what is known as a "converter" before the current reaches the lamp. I am also credibly informed that considerable dampness exists on the walls of the Senate Chamber, and I am therefore impelled to call your attention to the existence of a very serious danger which threatens not only the destruction of the building by fire, but the life of persons coming in contact with the lamps, wires or other apparatus. The object of the "converter" above mentioned, is to reduce the dangerously high pressure before it enters the lamp; but the prevalence of moisture will cause condensation in the converter itself, the result of which will be that this high tension alternating current will be transferred directly to the lamp, in which case instantaneous death would be caused to any one handling the lamp or its attachments. I would farther call your attention to the fact that the only object in using this high tension current is to effect a small saving in the cost of the copper conductors in the first installment of the plant, while the cost of operating the plant is increased, thereby incurring an additional annual expense *in perpetuo*, by reason of the loss of current in the converters.

It is claimed by the adherents of the alternating system that their current is no more dangerous than the direct system; but recent exhaustive experiments have proven that while 1000 of pressure of the direct current may be taken with impunity, 200 units of pressure of the alternating system will cause instantaneous death. In support of this statement, I would particularly call your attention to the enclosed copy of a report of certain tests made by Mr. Harold P. Brown, a well-known Electrician of this city, in the Laboratory of Columbia College, under the auspices of Dr. Cyrus Edson, of our New York Board of Health, and other well-known authorities. I also enclose a copy of a letter addressed by the Hon. A. B. Cornell, of this city, to Mayor Hewitt, and a copy of a letter from Mr. Brown to Mr. Cornell, to all of which I would invite your careful attention, and which I am sure cannot fail to interest you.

I need not add that should you at any time desire any further or more specific information upon this subject, I shall be pleased to hear from you.

Yours very truly,
(Signed.) EDWD. H. JOHNSON,
President.

Endorsed as follows:—

"Respectfully forwarded to the Hon. Mr. Aldrich, Chairman of the Committee on Rules, with the suggestion that the matter would seem to be one worthy of early and close scrutiny.

Oct. 1, 1888. GEO. F. EDMUNDS.

GEO. C. MAYNARD,
Telegraphist and Electrician, No. 1409 New York Avenue.
Washington, D. C., Oct. 22, 1888.

EDWARD CLARK, ESQ.,
Architect U. S. Capitol, Washington, D. C.

Sir:—Acting upon your instructions, I have made a cursory examination of the Incandescent Electric Lighting apparatus in the Senate Wing of the Capitol Building, for the purpose of gaining information which would enable me to answer your question whether, in my opinion, "there is any danger attending the use of the apparatus."

This examination has led me to the conclusion that there is danger in such use.

The engineer in charge of the lighting plant very politely acceded to your request to explain its workings to me, and Mr. Jones, the Senate engineer, showed me over the routes of the wires, explained their construction, etc., etc. The former stated that each of the two dynamos, when running under normal conditions, develops a current of 1000 volts. I believe a current of such power is liable to cause the death of a person subjected to its effects.

The current from the dynamos is carried through a system of wires to a large number of converters located in various places in the basement of the building, and in the space over the ceiling of the Senate Chamber. These converters and much of the wire leading to them, are placed where there must necessarily be a great deal of work of various kinds done, and I think, that the risk that workmen employed in doing it may accidently and unknowingly make contact, directly or indirectly, with the apparatus and receive a dangerous current, is very great, and this risk, it appears to me, is liable to increase with lapse of time. A large number of other wires run in close proximity to the wires of the lighting system, some of them being stapled to the wooden casing covering the latter, and this complication, I think, renders it quite probable that the current may be directed from its proper channels into dangerous ways.

Your inquiry, did not, as I understand, relate to the question of danger from fire which might result from the use of the lightning system, but this is a matter which is also worth your attention.

Very respectfully,
Your obedient servant,
(Signed.) GEO. C. MAYNARD.

TREASURY DEPARTMENT, OFFICE OF THE SECRETARY.
Washington, D. C., October 22, 1888.

EDWARD CLARK, ESQ.,
Architect of the U. S. Capitol, Washington, D. C.

Sir:—Referring to the subject contained in the accompanying papers, submitted to you for my consideration and herewith respectfully returned, viz.—a communication from the president of the Edison Electric Light Co., of New York, and a report of tests made by Harold P. Brown, E. E., of that city, relative to the dangerous character of alternating currents, &c., the above having reference to the electric lighting system now in use in the Senate Wing of the Capitol. The system referred to is that known as the Westinghouse, alternating with a primary voltage of 1,000 volts reduced in "converters" and distributed at about 50 volts.

The transference of the high tension current to the distributing service through any accidental short circuiting in the "converters" or otherwise, would seriously imperil human life.

Regarding the deadliness of the alternating as compared with the "constant" current, the report of Mr. Brown, from his standing, and that of his associates, is deserving of fullest credence.

The danger to be apprehended in the use of the system referred to, is, however, extremely remote. The converters are not exposed to unusual dampness, and the system is carefully installed. The immunity from harm is a matter of insulation and thorough installation, by the contractors or owners, intelligence and carefulness on the part of those connected with the plant, and the absence of a disposition to meddle by those *not* connected therewith.

Given the above conditions and such a plant is as safe as any of the various forms of energy at high potential, but which it is absolutely impossible to remove from such risks as are inseparable from human management thereof.

Very respectfully,
(Signed.) J. E. POWELL,
Inspector Electric Light Plants, &c., Treasury Dept.

THE AMERICAN BELL TELEPHONE COMPANY ADJUDGED LIABLE TO TAXATION IN NEW YORK.

It was decided by the General Term of the Supreme Court, New York, November 23, that the American Bell Telephone Co. although a Massachusetts corporation, was liable to taxation on its business in this state. The state claims taxation on the earnings of the company and upon the amount of the capital stock employed in this state, with 10 per cent more for default in payment. Chief-justice Van Brunt and Justice Daniels hold that the company is liable to taxation, and judgment was given for $34,478.90.

In his opinion, Judge Van Brunt holds that the company is not liable prior to 1885, when the law was amended making these corporations liable only for a portion of the capital stock employed in this state, and not the whole of the companys' capital stock. Judge Daniels says that the property of the company, even when it passes into the hands of other companies for use for any period of time, never passes from the control of the owners, who enjoy the protection of the state. The company is, therefore, clearly liable to taxation. Judge Brady coincides with Judge Daniels.

ACCUMULATORS MEET AN EMERGENCY.

Owing to an accident to the steam plant in the residence of J. Pierrpont Morgan, 36th street and Madison avenue, New York city, several weeks ago, he was left without any means of illumination except candles, gas having been abolished some time previously, and as he expected to give a large dinner party the following evening it was necessary to take prompt measures to remedy the defect. The Electrical Accumulator Company having a supply of accumulators for temporary lighting, began the work of charging them at 4 o'clock in the afternoon, finishing at 12 o'clock noon the next day. The accumulators (60 "15A" type) were then placed in crates, loaded on trucks and carted from their Newark factory to Mr. Morgan's house (10 miles), set up with necessary switches and appliances and at 6 o'clock the light was turned on, thus supplying Mr. Morgan with electric light in ample time for his entertainment. He has expressed himself has greatly pleased with the success of the experiment, and has now arranged for a permanent installation of accumulators as an adjunct to the Edison direct lighting plant, thus supplying him with means of illumination during such periods of time as the direct service from any cause may not be available, and also on special occasions, such as entertainments, etc., when all, or nearly all, of the lamps in the house may be required, and which latter contingency could not otherwise be provided for except by the use of a larger dynamo.

THE TELEPHONE.

THE LOWTH STETHO-TELEPHONE Co., of Chicago, claims that its telephones escape the fundamental claim of the Bell patent. The Lowth telephone is said to employ the actual vibrations of the vocal organs to actuate its mechanism, through the impact of a button placed against the throat in the vicinity of the larynx, and is therefore said to be independent of the air vibrations used to actuate the diaphragm of the Bell telephone. It is doubtless superfluous to direct the attention of the inventor and promoters to the effect of the presence of the casual blue-bottle fly upon stethoscopic apparatus, illustrated in Dr. Oliver Wendell Holmes' touching verses on the subject.

ELECTRIC LIGHT AND POWER.

FORT WAYNE, IND.—A despatch to the *Evening Telegram*, November 23, reports the destruction by fire of the extensive works of the Fort Wayne Jenney Electric Light Co. The entire plant, including the old and new buildings and the plant of the Star Iron Tower Co., were entirely destroyed. The loss on buildings, stock and machinery is given at $300,000 upon which there is an insurance of $148,000. The origin of the fire is supposed to have been spontaneous combustion.

THE HEISLER ELECTRIC LIGHT CO.'S LIST OF CENTRAL STATIONS USING THE HEISLER INCANDESCENT LONG-DISTANCE SYSTEM, ERECTED OR CONTRACTED FOR TO NOVEMBER 17TH, 1888.

The generating capacity is based on 30 candle lamps as a standard. Lamps in actual service vary from 10 up to 100 candle.

THE HILL CLUTCH WORKS, Cleveland, O., will furnish the entire power plant for the electric lighting station of the New Bedford Gas Co., New Bedford, Mass. They designed the plant, making complete drawings of everything, and have secured the contract for the work.

THE WESTINGHOUSE ELECTRIC CO. enters the field of arc lighting through its acquisition of the entire capital stock of the Waterhouse Electric and Manufacturing Co. The machinery for the manufacture of the arc apparatus of that company is being erected in the works of the Westinghouse company at Pittsburgh, and preparations are being made to conduct the manufacturing on an extensive scale.

THE WATERHOUSE COMPANY has about 5,000 arc lights in operation and a number of important stations.

THE THOMSON-HOUSTON ELECTRIC CO. reports the following new business :—

	Arc lamps.	Incandescent lamps.
Chattanooga, Tenn	200	
Findley, Ohio	185	
Wood, Brown & Co., Philadelphia, Pa	60	
Young, Smith & Co., Philadelphia, Pa	60

Malden, Mass		500

A SUCCESSFUL test was made November 24, at Virginia, Nevada, of a 60-stamp quartz mill, which was run by Brush motors, the current being obtained from dynamos located in the Sutro tunnel, 1,700 feet below the surface; these dynamos being driven by six large Pelton water wheels with a pressure of 680 pounds to the square inch. This water power does not equal, however, that of the Truckee river, 16 miles distant from the Comstock mines, and it is probable that before long, hundreds of stamp mills will be in operation by electric motors, which have proven the only kind of power sufficiently economical to permit of the working of low grade ores at a profit. It is said that over $40,000,000 has been spent in a fruitless endeavor to secure the above result.

Foreign.

Australia.—THE ELECTRIC LIGHT PLANT AT THE INTERNATIONAL EXHIBITION.—The Centennial International Exhibition, which was held in commemoration of the centenary of British settlement in Australia, was formally opened upon August the first, last.

The exhibition covers 35½ acres of space, throughout which are distributed 1,000 arc lights of the Brush system, and 2,000 16-c. p. Swan incandescent lamps. The entire electrical installation was done by the Australian Electric Light, Power and Storage Co., and is claimed to be the largest installation of its kind.

Six engines of 200 h. p. each are employed to drive a line of shafting 160 feet in length, with which the dynamos—49 in number—are connected.

Germany.—ELECTRIC LIGHTING.—The work done by the Edison company in Berlin, is said to be so good that the public and the municipal authorities have perfect confidence in their ability to extend their central station work still further, and a concession has been given to the company for the establishment of two new stations—one in the centre of the town and the other in the south-east quarter, where most of the engineering works and other factories are situated. Both stations must be ready within two years, and each must be able to supply current for 6,000 lamps burning simultaneously. The station in the centre of the town will eventually be increased to a capacity of 24,000 lamps, and the other station will be increased to 12,000 lamps, the annual increase to be not less than 6,000 and 3,000 lamps respectively. All the cables required in connection with these stations must be in position by the end of 1892, and the supply of current within both districts will be compulsory, provided the customer is willing to take the light for at least one year. The network of cables to be laid down in connection with these stations is very complete, and practically comprises all the streets of the respective districts, some small and unimportant side streets alone excepted. In view of this extension of their business, the Edison company propose to increase their share capital at present by $750,000, and later on by $1,500,000. The electric light installation in the Monopol Hotel of

Berlin, which comprises 1,000 lamps, will shortly be in action. The work has been executed by the Berliner Maschinenbau-Actien-gesellschaft, under the superintendence of Herr Beringer. The current is supplied by two 80 h. p. dynamos, each direct coupled to a twin engine. The dynamos are of the eight pole disc type, and are compound-wound. Steam is supplied by two Babcock & Wilcox boilers, having collectively a heating surface of 2,400 square feet.

MANUFACTURING AND TRADE NOTES.

MESSRS. JAS. W. QUEEN & Co., Philadelphia, so long and widely known as makers and importers of physical and chemical apparatus, are making the electrical department of their business a prominent feature. Their electrical testing apparatus covers a large variety of instruments, of both old and new types; as was very obvious to all who examined their extensive exhibit at the electric light convention in August.

THE HAWKEYE ELECTRIC Co. has been re-organized, and will be removed from Oskaloosa, Iowa, to Davenport, Iowa, in order to take advantage of the better facilities for manufacturing and shipping which the latter city affords. Mr. William Bowen will continue as general manager, and Mr. Frank Thone, as electrician.

MR. A. A. MCCREARY, of 15 Cortlandt street, has placed upon the market a novel reflector for incandescent lights. It is simple in design. A combination of ground glass and silver leaf is used to secure an equal diffusion of light, entirely eliminating the glaring effect of the naked lamp.

MR. W. R. RATHVON, of Denver, Col., announces that he is about to open an electrical supply house in that city.

THE HARRISBURG CAR MANUFACTURING Co., foundry and machine department, report large sales of engines, boilers and machinery during the present season. The Ide engine made by them finds much favor for electric light stations. Among 20 engines ordered during October and to November 9, are two 150 h. p., Reading, Pa., Electric Light Co.; one 30 h. p., Middletown Delaware Electric Co., and one 100 h. p., Augusta, Ga., National Exposition.

MESSRS. C. E. JONES & BROTHERS, Cincinnati, send us a pamphlet describing a small dynamo of 18-light capacity, made by them for use wherever a small isolated plant is desirable. The machine is very fully described and illustrated in detail, with particulars of dimensions, etc. The pamphlet will prove interesting to young students and experimenters, as well as to many people who want electric lighting outfits on a small scale. There is obviously a very considerable field for the use of outfits of from 10 to 20 lamps—in stores, offices, small workshops, even residences, where a suitable supply of power is available.

THE UNION SWITCH AND SIGNAL Co. has arranged for the exclusive right to manufacture and sell a new form of car buffer invented by Mr. George Westinghouse, Jr., which it is claimed will meet a want heretofore unfilled; namely, a device offering resistance to the inward movement of the draw-bar sufficient to absorb in itself the momentum of the load in ordinary working in such a way that the shock and consequent injury to the car, heretofore considered unavoidable, will be obviated.

The device consists of a cast-iron box containing a number of thin plates secured to it, and a like number of thin plates placed between those in the box and attached to movable pieces against which the draw-bar presses. When the draw-bar is pressed inwardly these thin plates are, by a simple wedge device, clamped or squeezed together so as to offer an immense frictional resistance to further inward movement, which together with the resistance of the main springs (the same as heretofore used), absorbs such an amount of momentum that it is possible to run one car into another at a speed of 8 or 10 miles an hour without fully exhausting the frictional resistance and compression of the springs.

Not only do the friction plates of the buffer offer an immense resistance, but the reaction of the main springs is prevented, thus assisting materially to decrease the risk of breaking trains in two. The apparatus is simple in construction, and is applicable to any form of draw-bar, but will be particularly valuable in connection with the Janney type of coupling, which does not at all times admit of the action of the dead blocks.

The apparatus has been designed with reference to securing uniformity in draw-gear, and is applicable to all classes of cars, freight and passenger, and its peculiar construction admits of a new method of attaching draw-gear, which will give all the practical effect of a continuous draw-bar, if desired; and the saving effected in attaching the apparatus is nearly equal to the cost of the special casting and frictional parts.

THE JULIEN ELECTRIC Co. report largely increased sales of their storage battery. From November 1st to the 16th, eleven (11) installations have been sold, amounting in all to 1,540 accumulators—thought to be the largest sales probably ever made here or abroad in the same length of time by any company engaged in storage battery business.

Ontario, Cal.—Ontario & San Antonio Heights Ry. Co.—*Pr.*, Chas. Frankish; *Sec.* and *Treas.*, D. McFarland; 8 mi.; g. 4-8½; 34 lb.; 4 c.; 3 m.; overhead cond. DAFT.

Ottawa, Ill.— 6 mi.; 8 m. c.; overhead. THOMSON-HOUSTON.

Philadelphia, Pa.—Lehigh Ave. Ry. Co.—*Pr.*, J. T. Banting; *Sec.* and *Treas.* J. McK. Barron; 6 mi.; g. 5-2½; 47 lb.; storage.

Port Chester, N. Y.—P. C. & Rye Beach St. Ry. Co.—*Pr.*, F. H. Skeele; *Sec.*, E. H. Cook; *Tr.*, C. D. Newton; *V. P.*, M. Dillon; *Supt.*, T. M. Burt; 3 mi.; g. 4-8½; 38 lb.; 5 m. c.; overhead cond. DAFT.

Reading, Pa.—Reading & Black Bear Ry.—1½ miles; 2 m. c.; overhead cond SPRAGUE.

Revere, Mass.—Lynn & Boston R. R.—Ocean Ave. line; overhead cond. THOMSON-HOUSTON.

Richmond, Va.—Richmond City Ry. Co.—*Pr.*, J. L. Schoolcraft; *Treas.*, Walter Kidd; *M.*, C. M. Bolton; *Supt.*, Charles Selden; 7½ mi.; g. 4-8½; 30-40 lb.; 50 m. c.; overhead cond. SPRAGUE.

Rochester, N. Y.—Rochester Elect. Ry.—*Pr.*, A. T. Soule; *Sec.*, J. B. Perkins; 9 mi.; 4-8½; 40 lb.; 20 c.; 8 m.

St. Joseph, Mo.—Wyatt Park Ry. Co.—*Pr.*, J. M. Huffman; *Sec.*, I. R. Williams; capital, $300,000; 5 mi.; g. 4-8½; 10 m. c.; overhead cond.; 8 Sprague cars. SPRAGUE.

St. Louis, Mo.—Lindell Ry Co.—*Pr.*, J. H. Lightner; *Supt.*, G. W. Baumhoff; *Eng.*, E. J. Bagnall; —— mi.; g. 4-10; 65 lb.; 1 m. c.; 2 m.; 8 p. c.; storage bats.

Sacramento, Cal.—Sac. Elect. Ry. Co. The Central Street Railway Co.—*Pr.*, L. L. Lewis; *Sec.*, E. K. Alsip; *Tr.*, F. Miller; *Supt.*, J. B. Austin; *Eng.*, ——; 13 mi.; g., 4-8½. Cars to be supplied by Electric Car Co, of America, Philadelphia.

Sault Ste. Marie, Mich.—S. St. M. St. Ry. Co.—*Pr.*, E. M. Lacy; *Sec.*, F. Ryan; *G. M.*, L. G. Cody; 2 mi. FISHER.

Sandusky, O.—Sandusky St. Ry. Co.—*Pr.*, Chas. V. Olds; *Sec.* and *Treas.*, A. C. Moss; *Supt.*, Clark Rude; 4 mi.; g. 4-8½; 32 lb.; 6 m. c.; overhead cond.; 6 Sprague cars. SPRAGUE.

Scranton, Pa.—The People's St. Ry.—*Pr.*, W. Matthews; *Sec.* and *Tr.*, H. E. Hayd; *Supt.*, F. Pearce; 10 mi.; g. 4-8½; 20 m. c.; overhead cond. SPRAGUE.

Seattle, Wash. Ter.—Seattle Electric Ry.—5 mi.; 3 m. c.

South St. Paul, Minn.—So. St. Paul Rapid Transit Co.—*Pr.*, A. E. Clark; *Sec.* and *G. M.*, J. H. Lawrence; (Enos elevated railway); 8 mi. 40 and 56 lb.; 10 m. c.; track conductors. DAFT.

Springfield, Mo.—2 mi. FISHER.

Steubenville, O.—Steubenville Electric Ry. Co.—2¼ mi.; g. 4-8½; 40 lb.; 7% grade: 10 m. c.; overhead cond. SPRAGUE.

Sunbury, Pa.—Sun. & Northumberland St. Ry. Co.—*Pr.*, H. E. Davis; *Sec.*, L. H. Kase; *Tr.*, S. P. Wolverton; 3 mi.; 4 c.; overhead cond.

Syracuse, N. Y.—Third Ward Ry. Co.—*Pr.*, Wm. B. Cogswell; *Sec.* and *Treas.*, W. S. Wales; *G. M.*, H. McGonegal; 4 mi.; g. 4-8½; 8 m. c.; 4 p. c.; steam power; sta. 250 h. p.; overhead cond. THOMSON-HOUSTON.

Tacoma, W. T.—Tacoma St. Ry.—*Pr.*, N. Bennett; 5 mi.; 4 m. c.; overhead. SPRAGUE.

Topeka, Kas.— 14 mi.; 30 m. c.; overhead. THOMSON-HOUSTON.

Worcester, Mass.—Worc. & Shrewsbury—(To be changed from steam to electricity); 2.7 mi.; g. 3; overhead cond. DAFT.

RECAPITULATION.

Roads Now in Operation,	52
Roads Constructing or Under Contract,	47

Notes.

ANSONIA, CONN.—The Derby Horse Railway Co., operating with the Van Depoele electric system, is about to increase its equipment by the addition of considerable Thomson-Houston apparatus.

DES MOINES, IA.—The electrical equipment furnished by the Thomson-Houston company for the Broad Gauge Street Railway Co., is almost ready to be put in operation.

NORTH ADAMS, MASS.—The electrical equipment of the Hoosac Valley Street Railway under the Thomson-Houston system, which it has been intended to defer until next year, will now probably be completed this season.

SYRACUSE, N. Y.—The Third Ward Street Railway Co., (Thomson-Houston system) was to be started about December 1st. The equipment and overhead construction are first-class, and railway men of central New York are looking forward with much interest to see it put in operation.

TOPEKA, KANS.—Work is progressing rapidly for the installation of the Thomson-Houston plant to operate the Rapid Transit Railway. This road when put in operation will be the largest electrical railway in the world, being 14 miles in length.

WICHITA, KANS.—Within the past month the new Thomson-Houston railway has been put in operation here, and is working more successfully than anyone in Wichita believed was possible for an electrical equipment to do, the faith of Wichita citizens in electrical propulsion having been greatly shaken by the failure and removal of a former electrical railway outfit there.

The overhead construction is one of its most striking features, the handsome pole lines affording no cause for objection on the score of disfiguring the streets.

THE SPRAGUE ELECTRIC RAILWAY AND MOTOR CO. has been at work for some time past upon a new design of motor, and several improvements in gearing. The new motor, which will be termed the "Boston," has a new method of winding. The motors are made from 7½ to 15 horse-power. The former method of distributing the weight of the motor and the use of double compression springs is retained. A slight change is made in the method of gearing, and the gears are of vulcanized fibre, thus securing elasticity and noiselessness, and at the same time retaining sufficient strength. The West End Railway, of Boston, is to be equipped with the "Boston" motor as soon as they are manufactured.

A VERY successful demonstration of the possibilities of electric traction for the elevated railroads was given on the evening of November 26, by the the Daft Electric Light Co. The motor car, called the Benjamin Franklin, was attached to three regular passenger cars, containing invited guests to the number of 100, at the 14th street station of the 9th avenue road, and a run was made to 42d street and back. The ordinary speed of the elevated trains was maintained, and the ease with which the train was started and stopped, as well as the entire absence of smoke and smell were commented upon favorably by all present. The trip was made in the midst of a driving rain and under what were considered unfavorable conditions, and the complete success of the trial was, therefore, a source of greater gratification than it would otherwise have been. The motor weighs 10 tons, and it is claimed is as powerful as the 18 ton engines now in use.

Mr. H. M. Hawkesworth, manager of the Daft company, conducted the test. Among those present were noticed: Assistant Manager Campbell, of the Manhattan road, A. H. Van Depoele, E. B. Hyde, Sidney Dillon, H. C. Havemeyer, Robert Lenox Belknap, and Dr. Beckwith.

OMAHA AND COUNCIL BLUFFS.—The electric railway between Omaha and Council Bluffs has been opened for general passenger traffic, and is now running to the satisfaction of its owners and the admiration of the general public.

The road is nine miles in length, and at present is operating 16 motor cars and 16 cars without motors, each motor car towing one of the others. The cars are operated in a manner quite unusual on street railways. They are made by the Pullman Palace Car Co., and are connected by the vestibule device, in use for the first time here on street railway cars; they are very popular, and it is fully believed that this method will ere long come into more general use.

Although the motors work equally well in either direction, a loop is made at each end of the track, to permit the motor car to be always ahead. This road opens a new means of rapid transit between Omaha and Council Bluffs, which is highly appreciated by the residents of the two cities, they having been previously compelled to travel by special trains on the Union Pacific Railroad, which ran once an hour, and upon which 25 cents was charged. The fares upon the new line have been reduced to the usual street railway rates. A speed equivalent to that of the steam road is made over a large portion of the track lying between Council Bluffs and the bridge over the Missouri river.

Great credit is due Mr. T. J. Evans and his associates in carrying through this entire project of rapid transit between the cities, they having expended not less than half a million dollars in constructing a magnificient bridge, 3,000 feet in length, over the Missouri river. No expense has been spared in making the railway one of the finest, if not the best, electric railway in the world.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From October 23 to November 13, 1888 (inclusive).

Alarms and Signals:—*Electrical Continuity Vibrator*, G. F. Milliken, 391,547, October 23. *Detachable Circuit-Closing Device for Electric Bells and Annunciators*, J. D. Randall, 391,917, October 30. *Police Alarm System*, J. C. Wilson, 392,248. *Magneto-Signaling Apparatus*, M. W. Long, 392,443, November 6. *Combined Fire-Alarm and Telephone Telegraph*, G. C. Hale, A. Barrett and J. Zentner, 392,604. *Auxiliary Fire-Alarm Box*, E. L. Slocum, 392,641. *Signaling Apparatus*, W. Trafford, 392,766. *Individual Signaling Apparatus*, C. N. Talbot, 392,832. *Message and Time Recorder*, J. C. Wilson, 392,888. *Automatic Fire-Extinguisher and Alarm*, I. T. Dyer, 392,951. *Annunciator*, F. Ritchie, 392,970, November 13.

Clocks:—*Clock Synchronizer*, A. G. Wiseman, 391,446, October 23. *Electric Self-Winding Clock*, V. Himmer, 391,969, October 30. *Electric Regulating and Hand-Setting Mechanism for Clocks*, W. S. Scales, 392,230, November 6.

Conductors, Insulators, Supports and Systems:—*Cable Hanger*, E. J. Hall, 391,605. *Conduit for Electric Wires*, M. Dallas, 391,587. *Electric Cable Joint*, J. E. Cuff, 391,517, October 23. *Machine for Making Conduits*, G. Richardson, 392,069. *Electric Conductor*, H. F. Campbell, 392,103. *Insulator for Electric Conductors*, J. C. Love, 392,127, October 30. *Cover for Man-Hole Chambers of Underground Conduits*, M. R. Muckle, Jr., and W. H. B. Teamer, 392,877, November 13.

Distribution:—*System and Apparatus for Electrical Distribution*, M. M. M. Slattery, 391,923. *Electric Distribution by Alternating Currents*, C. Zipernowski, M. Deri and O. T. Blathy, 392,090. *Apparatus for Electrical Distribution*, G. B. Fraley, 392,114, October 30. *Transformation and Distribution of Electric Energy*, W. J. McElroy, 392,213, November 6.

Dynamos and Motors:—*Electric Motor*, J. Doyle, 391,590, October 23. *Electric Motor*, W. E. Hyer, 391,797. *Regulator for Dynamo-Electric Machines*, S. D. Field, 391,954, October 30. *Regulator for Alternating-Current Generators*, R. P. Sellon and W. M. Mordey, 392,370. *Operating Alternate-Current Motors*, W. Stanley, Jr., 392,470. *Alternate-Current Electric Motor*, same, 392,471. *Commutator-Bar for Dynamo-Electric Machines*, C. E. Billings, 392,490, November 6. *Insulation of Cores of Dynamo-Electric Machines*, B. Bidwell 392,660. *Dynamo-Electric Machine*, E. Thomson, 392,765. *Automatic Governor for Dynamos*, E. B. Coburn, 392,855. *Regulation of Electric Motors*, W. Stanley, Jr., 392,890. *Method of Synchronizing Electric Motors*, F. J. Patten, 392,930. *Synchronizing System for Electric Motors*, same, 392,967, November 13.

Galvanic Batteries:—*Galvanic Battery*, H. J. Brewer, 391,505, October 23. *Carbon Battery*, J. B. Wallace, 392,886, November 13.

Ignition;—*Electric Gas Lighter*, J. H. Lehman, 392,440, November 6. *Electric Gas Lighter*, H. A. Cleverly, 392,665. *Electric Machine for Lighting and Extinguishing Gas*, G. E. Thaxter, 392,701, November 13.

Lamps and Appurtenances:—*Electric Arc Lamp*, S. E. Nutting, 391,761. *Incandescent Electric Lamp*, T. A. Edison, 391,596. *System of Electric Lighting*, same, 391,595. *Arc Lamp*, H. W. Libbey, 391,477, October 23. *Manufacture of Incandescent-Lamp Filaments*, J. W. Packard, 391,815. *Flashing Apparatus for Carbon Filaments*, same, 391,816. *Method of Connecting Filaments to Leading-in Wires*, H. Lemp, 392,158. *Apparatus for Mounting Filaments of Incandescent Lamps*, same, 392,159, October 30. *Mast-Arm for Electric Lights*, C. W. Russell, 392,228, *Arc Lamp*, J. C. Young, 392,393. *System of Incandescent Lighting*, C. Heisler, 392,513. *Arc Light Carbon*, J. J. McTighe, 392,520, November 6. *Electric Lamp Switch*, C. G. Perkins, 392,633. *Incandescent Lamp Socket*, T. Coad, 392,666, November 13.

Measurement:—*Electric Measuring Instrument*, A. H. Eddy, 391,592, October 23. *Electrical Measuring Instrument*, V. H. Emerson, 392,018, October 30. *Electro Plated Coil for Electrical Measuring-Instruments*, E. Weston, 392,385. *Electrical Measuring Apparatus*, same, 392,386 and 392,387. *Electric Meter*, P. Lange, 392,437. *Combined Electric Meter and Electric-Clock System*, same, 392,438. *Electric Meter*, same, 392,439. *Reflecting Galvanometer*, E. Weston, 392,476. *Galvanometer*, same, 392,477 and 392,478. *System of Electric Meters*, A. Wurts, 392,577, November 6.

Medical and Surgical:—*Electric Plaster*, H. P. Pratt, 391,720, October 23.

Miscellaneous:—*Arc-Extinguisher for Electric Switches or Cut-Outs*, A. H. Eddy, 391,594. *Automatic Commutator for Alternating Electric Currents*, same, 391,593. *Electric Switch*, W. B. Cleveland, 391,512. *Electric Potential Differentiator*, E. Thomson, 391,437, October 23. *Automatic Electric Heat Regulator*, W. A. Connelly, 391,783. *Method of and Apparatus for Dissipating Electricity in Delivering Sheets from Printing Machines*, W. C. Rossney and C. L. Hunt, 391,820. *Cut-Out for Electric Circuits*, H. C. McDill, 391,853, *Circuit-Closing Mechanism*, C. E. Ongley, 391,855. *Electric Switch or Cut-Out*, W. C. Bryant, 391,943. *Electrical Switch*, O. B. Johnson, 392,034. *Automatic Electric Switch*, I. L. Roberts, 392,167, October 30. *Electric Discharge Device*, R. Belfield, 392,400, November 6. *Electric Speed Governor for Water Wheels*, G. M. Lee, 392,679. *Coin-Controlled Electrical Weighing Scale*, W. R. Smith and A. L. Washburn, 392,698. *Electrical Circuit and Apparatus Guard*, I. H. Farnham, 392,724. *Electrical Apparatus for the Prevention of Incrustation*, M. Kotyra, 392,736. *Electric Circuit*, J. A. Barrett, 392,775, November 13.

Railways and Appliances:—*Railway-Train Indicator*, B. E. Waters, 391,568. *Electric Railway*, P. Wright, 391,447, October 23. *Electric Railway*, I. W. Heysinger, 391,792. *Motor Car for Electric Railways*, same, 391,793, October 30. *Railway Signal*, M. W. Long, 392,444, November 6. *Conduit for Electric Railways*, H. A. Chase, 392,664. *Electric Railway*, R. M. Hunter, 392,675. *Overhead Conductor for Electric Railways*, E. E. Ries, 392,757. *Electrical Railway*, O. Allen, 392,772. *Electric Railway*, B. Herwood, 392,863; I. Robbins, 392,971, November 13.

Storage Batteries:—*Machine for Making Battery Plates*, A. J. Madden, 391,542. *Automatic Circuit Changer for Secondary Batteries*, W. W. Griscom, 391,468, October 23. *Electrode for Storage Batteries*, G. H. Stout, 392,080, October 30. *Secondary Battery*, H. Walter, 392,244. *Method of Making Electrodes for Secondary Batteries*, C. H. Thompson, 392,573. *Electrode for Secondary Batteries*, C. H. Thompson, 392,574, November 6. *Automatic Switch for Secondary Batteries*, J. S. Sellon, 392,826, November 13.

Telegraphs:—*Telegraphy*, S. D. Field, 392,914, November 13.

Telephones, Systems and Apparatus:—*Telephone Exchange System*, C. E. Scribner, 391,762, October 23. *Individual Signaling Apparatus for Telephones*, E. Davis, 391,839. *Telephony*, W. W.
